Glossary and Acronyms

AASHTO: American Association of State Highway and Transportation Officials

AC: Asphalt Pavement

ACLM: Annualized Cost Per Lane-Mile

ADT: Average Daily Traffic

ASTM: American Society for Testing and Materials

ASI: Asset Sustainability Index

ACR: Asset Consumption Ratio

ASR: Asset Sustainability Ratio

Asset management: Asset management means a strategic and systematic process of operating, maintaining, and improving physical assets, with a focus on both engineering and economic analysis based upon quality information, to identify a structured sequence of maintenance, preservation, repair, rehabilitation, and replacement actions that will achieve and sustain a desired state of good repair over the life cycle of the assets at minimum practicable cost.

Asset Management Plan*:* A document that describes how a State DOT will carry out asset management. This includes how the State DOT will make risk-based decisions from a long-term assessment of the National Highway System (NHS), and other public roads included in the plan at the option of the State DOT, as it relates to managing its physical assets and laying out a set of investment strategies to address the condition and system performance gaps. This document describes how the highway network system will be managed to achieve State DOT targets for asset condition and system performance effectiveness while managing the risks, in a financially responsible manner, at a minimum practicable cost over the life cycle of its assets.

BMS: Bridge Management System

BrM: AASHTO's Bridge Management Software, formerly known as PONTIS.

Bridge deck: Decks are the horizontal portion of the bridge, usually made of concrete; the deck is atop the superstructure and includes the traffic-carrying surface.

Bridge superstructure: The portion of the bridge that supports the deck, spans the opening, and connects the substructure elements.

Bridge substructure: The portions of the bridge including piers and abutments that transfer the load from the superstructure to the foundations.

BRR: Backlog Reduction Ratio

CAR: Cost Accrual Ratio (CAR)

CE: Construction Engineering

CMAQ: Congestion Mitigation/Air Quality

Cracking: As measured by the Federal definition, cracking refers to the percentage of the pavement area that exhibits visible cracking.

Culvert: A buried structure supporting a roadway with a span of at least 20-feet in length

Department/ITD: The Idaho Transportation Department

ERM: Enterprise Risk Management

FAST Act: Fixing America's Surface Transportation Act

Faulting: A difference in elevation across a joint or crack usually associated with concrete pavement.

Federal-aid highways: A network of approximately 1 million miles of roads and highways out of about 4.1 million miles of public roads nationwide. Several categories of Federal Highway funds are eligible to be spent on the Federal-aid network. Most Federal-aid funds are not eligible off the Federal-aid system except for some bridge, safety, and transportation alternatives funds.

Federal Highway Administration (FHWA): The division of the U.S. Department of Transportation that oversees Federal highway programs.

Financial plan: As defined by FHWA, a financial plan means a long-term plan spanning 10 years or longer, presenting a State DOT's estimates of projected available financial resources and predicted expenditures in major asset categories that can be used to achieve State DOT targets for asset condition during the plan period, and highlighting how resources are expected to be allocated based on asset strategies, needs, shortfalls, and agency policies.

FWD: Falling Weight Deflectometer

GARVEE: Grant Anticipation Revenue Vehicle

GIS: Geography Information System

GPR: Ground Penetrating Radar

HDA: Highway Distribution Account

HFP: Highway Funding Plan

HPMS: Highway Performance Monitoring System

HSIP: Highway Safety Investment Program

IDI: Individual Distress Index

Interstate Highway System: A national network of 48,500 miles of freeways signed as Interstate Highways.

Investment strategies: Investment strategy means a set of strategies that result from evaluating various levels of funding to achieve State DOT targets for asset condition and system performance effectiveness

at a minimum practicable cost while managing risks.

IRI: The International Roughness Index (IRI) is a statistic used to estimate the amount of roughness in a measured longitudinal profile. It measures inches of roughness, or "bounce", per mile of road.

Idaho Transportation Department (ITD) Board: A board that oversees the operations of the Idaho Transportation Department. The Idaho Transportation Board establishes state transportation policy and guides the planning, development and management of the transportation network.

LCA: Lifecycle Cost Analysis

LCP: Lifecycle Cost Planning

LHTAC: Local Highway Technical Assistance Council

LRS: Linear Referencing System

Local highways: Streets and roads owned by the cities and counties, as opposed to ITD.

Measures: As defined by FHWA, measures are an expression based on a metric that is used to establish targets and to assess progress toward achieving the established targets.

MMS: Maintenance Management System

MPO: Metropolitan Planning Organization

MWP: Master Work Program

National Highway System (NHS): Is a network of 222,000 miles that include the Interstates as well as other major arterials.

NBI: National Bridge Inventory

OCI: Overall Condition Index

PCC: Portland Cement Concrete

PE: Professional Engineering

Performance Gap: FHWA defines a performance gap as the difference between a desired condition level, or target, and the actual condition.

PFT: Pavement Friction Tester

PMS: Pavement Management System

QC: Quality Control

RDQMP: Roadway Data Quality Management Program

Risk: The positive or negative effect of uncertainty on objectives.

Risk Management: The systematic process of managing risk.

RSI: Remaining Service Interval

Rutting: Rutting means longitudinal surface depressions in the pavement derived from measurements of a profile transverse to the path of travel on a highway lane.

S & C: Safety and Capacity

SHA: State Highway Account

SHS: State Highway System

SIPF: Strategic Initiatives Program and Fund

SPR: State Planning and Research

State of Good Repair: Means ITD is achieving the performance targets of Idaho's TAMP.

STBG: Surface Transportation Block Grant

STIP: State Transportation Investment Program

STP: Surface Transportation

TAMP: Transportation Asset Management Plan

TAMS: Transportation Asset Management System

TAP: Transportation Alternatives Program

Target: As defined by FHWA means a quantifiable level of performance or condition, expressed as a value for the measure, to be achieved within a time period required by the Federal Highway Administration (FHWA).

TECM: Transportation Expansion and Congestion Mitigation

VMT: Vehicle Miles Traveled

June 30, 2019

Peter Hartman
Division Administrator
Federal Highways Administration – Idaho Division
3050 N Lakeharbor Ln # 126, Boise, ID 83703

Dear Mr. Hartman,

On behalf of the Idaho Transportation Department, I approve and am submitting the Idaho Transportation Department 2018 Transportation Asset Management Plan (TAMP). Per the requirements of 23 CFR 515.11(a)(1),

The TAMP is one of four plans that ITD must produce under relatively recent Federal laws. The other plans address highway safety, congestion, and freight movement. The TAMP is limited to the conditions of bridges and pavements on the NHS. The TAMP describes in eight sections how ITD addresses the Federal asset management requirements, and more importantly, how it manages Idaho's critical highway network. FHWA regulations also require that the plan include descriptions of how seven processes were used to develop the plan. As a result, the plan includes not only conclusions and recommendations, but a description of the processes used to reach them.

The seven required processes are to:

1. Complete a performance gap analysis and to identify strategies to close gaps,
2. Implement life cycle planning,
3. Manage risks with a risk management plan,
4. Develop a financial plan covering at least a 10-year period,
5. Develop investment strategies,
6. Obtaining necessary data from NHS owners other than the State DOT,
7. Ensure the TAMP is developed with the best available data and that the State DOT uses bridge and pavement management systems meeting the requirements.

ITD requests that the FHWA – Idaho Division review and certify the reference document.

During the FHWA review process, please contact Jim Poorbaugh, ITD Asset Management Engineer, (james.poorbaugh@itd.idaho.gov) to address any questions or concerns.

Brian W. Ness
Director, Idaho Transportation Department

Executive Summary

Background

This is the federally required Transportation Asset Management Plan (TAMP) for the Idaho Transportation Department (ITD). It fulfills three objectives:

1. First, it satisfies detailed Federal requirements that each state must develop a TAMP that conforms to the contents of this document.
2. Secondly, it informs FHWA of how effectively ITD manages the bridges and pavements that comprise the National Highway System (NHS), which includes the Interstate. ITD manages many other assets that are not included in this plan because they are not required to be in the FHWA asset management plan.
3. Thirdly, this plan describes the current and forecasted condition of the NHS major roadway assets and presents processes the Department will utilize to manage them over the next decade.

The Idaho Transportation Department (ITD) is committed to the effective management of the state's highways to protect the public's safety and its massive investment in this important infrastructure. As part of this commitment, ITD has demonstrated a focus on the effective utilization of technology and asset management practices for over 40 years. The TAMP is focused on all NHS bridge and pavement assets within Idaho.

With respect to the NHS, ITD has stewardship over 96 percent of this network with local agencies managing the balance of the NHS. ITD annually collects performance data for the entirety of the NHS regardless of ownership and is committed to communicating the performance of the local agencies. ITD is developing dashboard and GIS tools to streamline accessibility to local agencies.

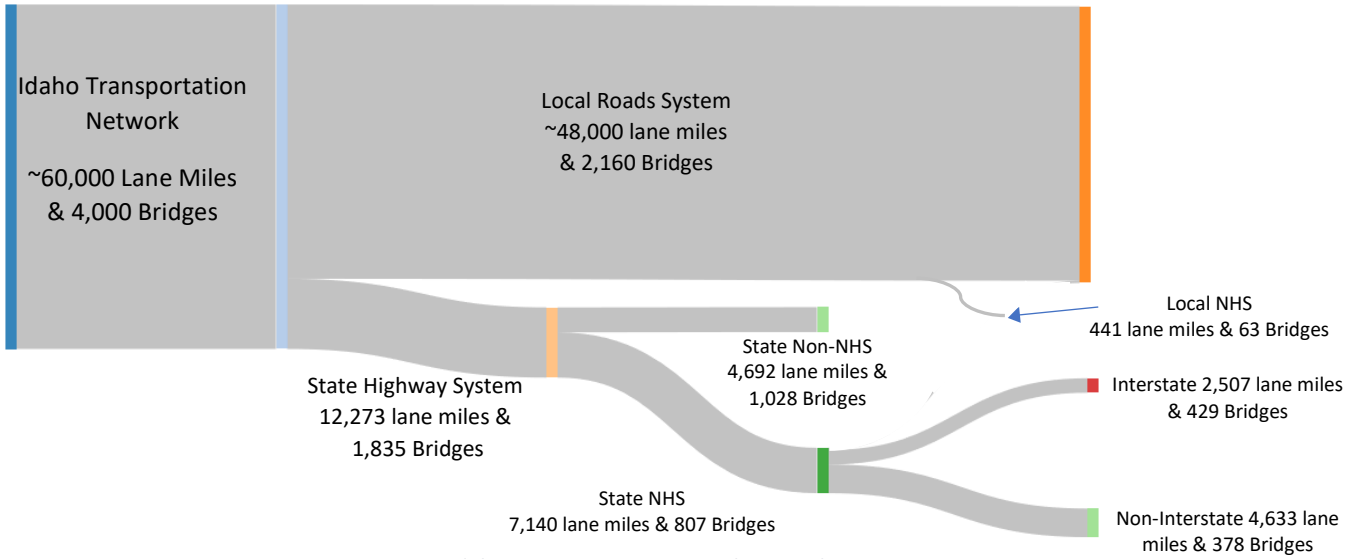

Figure 1: Idaho Transportation Network Asset Classes

ITD processes and procedures have always been, and will remain, equally applied across the entirety of the State Highway System (SHS). That is to say, ITD does not solely consider facility classification; rather, ITD looks through the lens of overall benefit to the visitors and residents of Idaho. This focus has placed ITD in the enviable position that the SHS roads and bridges are nearing or exceeding both Federal & ITD targets and goals. The NHS is a subset of 174,000 of the most important roads nationally. In Idaho, over 7,580 lane miles are on the NHS including the Interstates and major routes such as I-84, I-90, US 95, US 30, US 20, US 12, SH 55 and others. Congress emphasizes the condition of the NHS because of its freight and travel importance. Federal requirements require each state and territory to develop a Transportation Asset Management Plan (TAMP), ITD understands that the TAMP is the mechanism by which a state communicates their processes for monitoring, communicating, planning, financing and management of the assets they oversee. This plan focuses mainly on the NHS but ITD emphasizes its need to adequately maintain and manage all ITD jurisdictional roads to the best benefit of the citizens of Idaho. ITD understands the significance and importance of the NHS to the national transportation system. Confirmation and commitment to this view are demonstrated by well-established processes for project selection, which prioritize NHS assets for treatment and maintenance.

The Idaho's transportation network is one of Idaho's most valuable assets and is integral to the public's safety, mobility and economic opportunity. Idaho's transportation system includes a statewide network of more than 60,000 lane miles of roads and 4,000 bridges. Of these, ITD manages the SHS with over 12,273 lane miles of highways and 1,835 bridges. ITD manages just over 20 percent of all roadway miles in Idaho. However, the state system carries 55 percent of Idaho's total vehicle miles of travel (VMT). Although a small percentage of total lane miles within the State of Idaho, 4.2 percent, the Interstate highways alone carry 25 percent of miles traveled in Idaho. Within the SHS that ITD manages, the interstate accounts for 45 percent of the VMT. These assets are aging but as they do, they become even more important. From 1996 to 2018, vehicle miles travelled on the state highway system grew more than 38 percent. The Interstate system experienced a 55 percent increase in travel over the same period while the state system, excluding the interstates, experienced a 27 percent increase. This growth reflects the increasing mobility of Idaho's population and the growing importance of freight movement to our economy.

TAMP Section Summaries

The TAMP is organized to address specific Federal requirements. Each plan must include eight sections that describe the agency's asset management objectives, targets, and how it invests to achieve them. The organization and content of this plan are structured to satisfy the Federal requirements and to expedite Federal review. Failure to develop a certifiable plan can bring substantial Federal penalties and restrictions on how ITD can use Federal highway funds. The following sections provide a brief summary of the content of each section.

Beginning in June of 2019, FHWA annually will review ITD processes for consistency with this TAMP.

Chapter 1 - Objectives

Chapter 1 describes the specific objectives that ITD seeks to achieve. Its objectives are described in Chapter 1 and include:

1. Continually reduce fatalities

2. Provide a mobility-focused transportation system that drives economic opportunity
3. Maintain the pavement in good or fair condition
4. Maintain the bridges in good or fair condition

These objectives are focused on managing ITD's NHS bridge and pavement assets. ITD has other objectives relating to customer service, safety, and financial efficiencies that are outside the scope of this plan.

Chapter 2 - Asset Measures and Targets

This chapter describes ITD's asset management performance measures and targets. As required, the measures and targets are consistent with the department's objectives and help assess the condition and performance of ITD's highways. The FHWA performance measures and the target are shown in Table 1.

Table 1: ITD's NHS Performance Measures and Targets

Performance Measure		2 & 4 Year Targets	Reported Performance
Pavement	Interstate Percent Good	50%	65.6%
	Interstate Percent Poor	4%	0.2%
	Non-Interstate NHS Percent Good	50%	50.8%
	Non-Interstate NHS Percent Poor	8%	0.3%
Bridge	NHS Bridge Percent Good	19%	18.7%
	NHS Bridge Percent Poor	3%	3.2%

These measures and their targets are selected to provide benchmarks by which ITD can balance its investments. It intends to keep the percentage of poor bridges and pavements to manageable levels without setting targets that are unreasonably high and expensive to maintain.

Chapter 3 - Summary Description of Assets

This chapter describes the number, size, and condition of ITD's pavement and bridge assets. The majority of roads and bridges in Idaho are in very good condition. Idaho's conditions for bridges and pavements on the NHS are far better than minimum Federal condition levels. ITD expects to continue to sustain good NHS conditions for at least the next decade.

Idaho's transportation network includes a statewide network (including the Local System) of more than 60,000 lane miles of roads and 4,000 bridges. Of these, ITD manages 12,273 lane miles of highways on the SHS and more than 1,800 bridges. The Idaho NHS is comprised of a total of 7,581 lane miles which is comprised of approximately 7,140 state NHS lane miles and 441 local NHS lane miles. The State NHS includes 2,507 lane miles of interstate. There are 807 State system bridges on the state NHS (with an area of 8,148,547 sq. ft.). It is interesting to note that there are 63 local bridges (with an area of 667,474 sq. ft.) on the NHS. Currently only one of these bridges on the Local System is in poor condition with an area of 2,884 sq. ft. Table 2 summarizes ITD'a assets.

Table 2: Asset Summary

	Idaho	Federal
Population	Interstate, U.S. Route and State Highway System	National Highway System
Lane Miles	12,273	7,581
# of Bridges	1,835	870
Deck Area (sq. ft.)	12,659,970	8,816,021

Chapter 4 - Gap Analysis Process

This chapter describes ITD's lack of performance gaps. In fact, ITD far surpasses the minimum Federal standards set nationally for NHS bridges and Interstate pavements. FHWA defines a performance gap as the difference between a desired condition level, or target, and the actual condition. By the Federal definition, ITD has only a very small gap between its current asset conditions and its targets for asset conditions. That gap is that while ITD set a target of keeping 50 percent of the Non-Interstate NHS pavements in good condition and presently 48.9 percent are good. In Idaho, the amount of poor NHS bridge area is only 3.2 percent. (The percentage is calculated by bridge area, not by the number of bridges.)

For Interstate Highways, FHWA set a minimum condition level of no more than 5 percent of the lane miles to be in poor condition. In Idaho, only 0.20 percent of the Interstate lane miles are poor and only 0.30 percent of the NHS lane miles are poor. These percentages are based on recent FHWA measures of good, fair, and poor. They differ from the measure ITD and other states have used in the past.

In addition, this chapter discusses self-identified gaps in asset management processes. In order to strengthen future asset management plans ITD is taking steps to enhance several asset management processes. These include:

- Enhance pavement management model;
- Continue developing the BrM Bridge Management System;
- Assess the long-term consequences of the Non-Commerce Route treatments;
- Assess the Long-Term Needs of ITD's Large Structures.

Chapter 5 - Life Cycle Planning Process

This chapter describes ITD's lifecycle planning which is a process to manage an asset class over its whole life while minimizing costs and preserving or improving its condition. This chapter describes how ITD uses a mix of preservation, maintenance, rehabilitation, and timely replacement of assets to sustain them over their entire life for lower cost. Bridges and pavements perform better and cost less when timely repairs are made when assets are beginning to deteriorate. ITD describes how it attempts to lower the life-cycle cost of its assets through sophisticated pavement modeling that suggests what types of treatments are needed for each pavement. For bridges, ITD examines the details of inspection reports to match treatments to each structure's need.

Chapter 6 Risk Management Process

This section identifies risks considered in the plan and ITD's responses to those risks. FHWA defines risk as the positive or negative effects of uncertainty or variability upon agency objectives. Any plan that seeks for 10 years to meet condition targets for thousands of assets faces many uncertainties and risks. This chapter discusses many of the key risks facing the achievement of this plan's objectives, such as uncertain Federal funding, changing Federal rules, and a growing state population that increases demand for capacity-expanding projects. This chapter identifies the risks that could influence the asset management objectives and summarizes how ITD plans to manage those risks.

Specific risk categories reviewed included:

- Risks to maintaining assets in a state of good repair;
- Risks specific to maintaining pavements in a state of good repair;
- Risks to sustaining adequate investments for a state of good repair;
- Risks specific to maintaining structures in a state of good repair;
- Risks to having skilled staff sustain assets;
- Data and information risks;
- External and environmental threats.

The highest rated risks identified are:

- ITD may not be able to sustain assets in a state of good repair if:
    - …federal funding decreases;
    - …program selection priorities do not emphasize sustaining asset conditions;
    - …changes to Federal Rules consume more ITD resources;
    - …the donor/donee state financial balance changes.
- ITD may not achieve the pavement quality needed if ITD and contractor community do not adapt performance-based specifications.
- Bridges may deterioration if ITD does not dedicate adequate resources towards bridge maintenance.
- ITD may need to divert all bridge funds to a few large structures if ITD does not develop a program to address large structures needing rehabilitation/replacement in the next decade.
- Conflicting information caused by not having a single source of truth aligned with linear referencing system.

<u>One opportunity identified as part of the risk assessment was that if the PMS was improved then ITD would have an opportunity to improve and enhance modeling and forecasting of pavement performance.</u>

Chapter 7 - Financial Planning Process

This chapter describes the required 10-year financial plan to support the asset management strategies. For many years, ITD has produced the Idaho Transportation Investment Program (ITIP) that was a five-year list of revenues and projects. Recently, Idaho extended ITIP to seven years to improve the long-term planning for projects. This chapter discusses the ITIP and illustrates how it fulfills the Federal requirements for an asset management financial plan. FHWA requires a realistic financial plan that can pay for

the bridge and pavement investments included in the asset management plan. ITD extended the ITIP by 3-years assuming a flat projection (i.e. no growth in funding for either State or Federal funds) to serve as the federally required 10-year asset management financial plan.

Out of a total of $7.3 billion expected to be available between 2019 and 2028 (see Table 7-3: Forecasted Local Revenue Sources Plus Summary of All Sources on page 7-12), about $676 million is planned to be spent on basic pavement and bridge programs off the NHS. The ITD plans to spend $2.8 billion on the NHS. With almost $700 million will be spent on bridges, $888 million on NHS pavements, and the balance is divided among other programs on the NHS as shown in Figure 2. The remaining revenue goes to operations, maintenance, debt, salaries, local programs, safety and other needs.

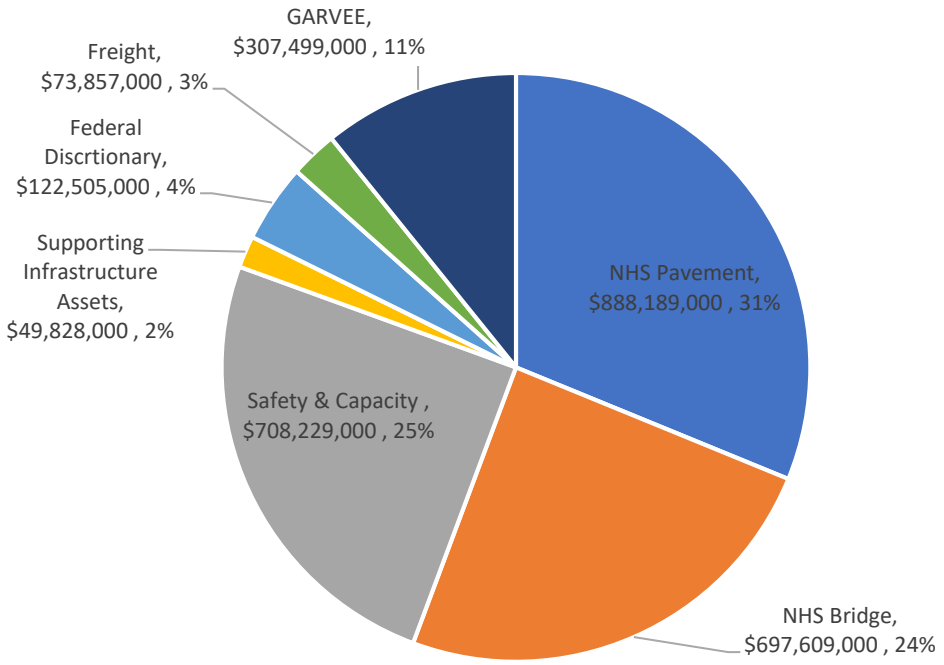

Figure 2: FY 2019-2028 Proposed ITD Ten Year NHS Funding Summary

Chapter 8 - Investment Strategies

This chapter describes ITD's investment strategies to achieve the plan's objectives, measures, and targets based upon analysis of various alternatives. ITD has balanced its expenditures across a mix of preservation and rehabilitation projects to achieve its targets while maintaining acceptable conditions on the entire SHS. This chapter describes the methodology used to forecast SHS pavement performance for a ten-year period considering various assumed funding levels. From these forecasts, NHS interstate and non-interstate performance information was extracted. SHS pavements annual funding levels forecasted were $100, $130, and $160 million. Based on the analysis ITD has determined that $130 million annual investment in SHS pavments is required to maintain NHS performance targets. A 10-year forecast is also presented for SHS bridges. The assumed funding level was maintained at the current level of $80-million annually. The forecast shows that ITD will achieve 80 percent of bridges will be in good condition around 2023.

Chapter 1 - Objectives

Idaho's transportation infrastructure is a deeply imbedded component of life in Idaho. Due to the large distances between population centers, the state's citizens use Idaho's transportation system to get to work, school, friends and recreation. They also rely on that system to bring goods to their stores, services to their doorstep, and to make sure the state's goods and services are delivered to the customers of the nation and the world. From the food they eat, to the letters they read, to the movies they drive to, Idahoans are empowered by transportation in complex and substantial ways.

Idaho's leaders and transportation officials understand the essential role transportation plays as a cornerstone for the state's economic and social health. The transportation department's mandate is to provide the people of Idaho with a transportation system that includes various means of travel. Idaho's transportation system is the backbone of the state's economy. Safe and efficient roads and bridges promote the expansion of Idaho's economy. The cost of doing business is affected by how well goods and people move across town, across the country and around the world. Thus, Idaho's economic performance is tied to the quality of our transportation system.

Goals

ITD developed the ITD 2017 -2020 Strategic Plan. This plan formally documents the department's mission, goals and objectives. The following are the organizational goals from the strategic plan that are also adopted as asset management goals:

1. Commits to having the safest transportation system possible
2. Provide a mobility focused transportation system that drives economic opportunity
3. Become the best organization by continually developing employees and implementing innovative business practices

Objectives

ITD' s asset management goals are supported by the following objectives from the ITD 2017- 2020 ITD Strategic Plan and which are adopted as the asset management plan goals:

1. Reduce Fatalities
2. Maintain the Pavement in Good or Fair Condition
3. Maintain the Bridges in Good or Fair Condition
4. Keep Highways Clear of Snow and Ice During Winter Storms
5. Hold Administration and Planning Expenditures Constant

ITD 2016-2020 Mission & Vision

MISSION:

Your Safety.

Your Mobility.

Your Economic Opportunity

KEY VISION ELEMENTS:

- Continually getting better with the goal of being the best transportation department in the country.
- Being transparent, accountable, and delivering on promises.
- Being more effective and saving costs through increased efficiencies.
- Providing remarkable customer service.
- Using partnerships effectively.
- Valuing teamwork and using it as a tool to improve.
- Placing a high value on employees and their development and retention.

6. Complete Project Designs On Time
7. Hold Construction Cost at Award to Programmed Budget
8. Hold Final Construction Cost to Contract Award

These objectives are congruent not only with ITD's mission statement but are consistent with the purpose of asset management, which is to achieve and sustain the desired state of good repair over the life cycle of the assets at a minimum practicable cost. Federal regulation says that the state's objectives should support the national transportation goals. By incorporating these objectives into the TAMP, the Idaho Transportation Department is contributing toward achievement of the National transportation goals enacted by Congress, which are:

1. **Safety -** To achieve a significant reduction in traffic fatalities and serious injuries on all public roads. ITD understands that keeping pavements and bridge assets in good condition directly contributes to improving the safety of the traveling public. For example, by monitoring and incorporating pavement rut depth into the ITD performance model ITD can actively plan maintenance activities or projects to mitigate which will greatly reduce the risk of a vehicle crash caused by wet weather.
2. **Infrastructure condition -** To maintain the highway infrastructure asset system in a state of good repair. Keeping good pavements good is important to ITD because the further a pavement deteriorates the more expensive they are to return to a state of good repair. ITD asset management systems consider infrastructure condition as the primary driver in program development.
3. **Congestion reduction -** To achieve a significant reduction in congestion on the National Highway System. As Idaho continues to experience rapid growth, ITD is committed to effective asset management that is coordinated with long-range transportation plans. This will ensure that ITD is not only maintaining assets in a state of good repair, that we are also seeking to consider expansion projects. Additionally, ITD understands that when assets are in a good state of repair, the public will be able to more effectively use facilities at higher speeds and capacities.
4. **System reliability -** To improve the efficiency of the surface transportation system. With effective life cycle management of assets, ITD is able to provide a transportation network, which the traveling public can rely upon to get them to their destination consistently and efficiently. This is demonstrated by standardized maintenance activities that keep good roads good and does not let them get to poor condition.
5. **Freight movement and economic vitality -** To improve the national freight network, strengthen the ability of rural communities to access national and international trade markets, and support regional economic development. ITD understands that maintaining assets in a state of good repair plays a significant role in addressing the demands of the commercial sector to increase truck weights and volume. ITD leverages performance data to improve pavement designs which in turn minimizes the increased funding requirements associated with repeated truck loads that shorten pavement life.
6. **Environmental sustainability -** To enhance the performance of the transportation system while protecting and enhancing the natural environment. At lower travel speeds, vehicles create more pollution through greater emissions. Incorporating asset management allows ITD to ensure that infrastructure condition issues are not contributing toward slower traffic speeds. Additionally, using effective life cycle maintenance strategies reduces the amount of material and energy required to be used over the life of the asset.

7. **Reduced project delivery delays -** To reduce project costs, promote jobs and the economy, and expedite the movement of people and goods by accelerating project completion. Coordinating pavement projects with other asset improvements limits disruption to the traveling public. Additionally, effective asset management applies lower impact treatments over time versus a few large impact treatments. This approach insures that ITD is limiting the disruption to the traveling public and completing work on time and on budget.

Chapter 2 - Asset Measures and Targets

Performance measures and targets are integral to ITD's successful implementation of asset management. Measures and targets drive commitment to and focus on accountability for assets. FHWA defines measures as an expression based on a metric that is used to establish targets and to assess progress toward achieving the established target. Idaho's performance measures are very similar in nature to FHWA's measures. In other words, the measure is "what we are measuring" such as pavement smoothness or traffic crash rates. The target is the numeric level of desired performance for each measure. An example of a measure is pavement smoothness as measured by the International Roughness Index or IRI. The target could be that no more than five percent of the lane miles be poor for the measure of roughness.

Idaho has been using performance measures since about 2006. Idaho's performance measures for pavements and bridges are slightly different from FHWA's. In this chapter, the differences will be explained and clarified. ITD recognized early on the value of using performance measures for asset management balanced by available funding and predicting future asset condition.

Idaho Measures and Performance Targets – Pavements

Similar to the FHWA measures, Idaho uses three measures to quantify performance; these are International Roughness Index (IRI), rutting depth, and Overall Condition Index (OCI). Developed as part of refinements to ITD's Transportation Asset Management System (TAMS), the OCI is unique to Idaho.

Idaho Measures - Pavement

The Overall Condition Index (OCI) provides an overall pavement serviceability measure. The OCI is the weighted average of many different pavement performance factors and there is flexibility to add other measure that are deemed relevant. The OCI varies between 100 representing the best possible pavement and zero (0) denoting the poorest possible pavement. The American Society for Testing & Materials (ASTM) has adopted this rating criteria as a standard for determining the pavement condition of a roadway.

Under the OCI method pavement distresses are recorded and quantified. The distresses recorded are related to the pavement type being considered. Table 2-1 shows the various distresses utilized during analysis. Quantification of distress type is based on extent and severity. These values are input, for each distress type, into an equation that yields an Individual Distress Index (IDI). When each individual distress type has been calculated, all of the IDI values are then input into the Overall Condition Index formula to compute the OCI for the pavement section. For each pavement type, two additional indices are computed with the methodology. Rigid pavement has the Slab Index and the Joint Index computed, while flexible pavements have the Structural Distress Index and the Non-Structural Index computed. The main function of these values is to assist in PMS

Table 2-1: OCI Distress Types

OCI Pavement Distress Types	
Flexible	**Rigid**
Fatigue Cracking	Slab Cracking
Edge Cracking	Joint Seal Damage
Transverse Cracking	Joint Spalling
Block Cracking	Faulting
Patch Deterioration	Map Cracking
Raveling	Studded Tire Wear

decision tree configuration and treatment selection. A copy of the AgileAssets Pavement Management System Engineering Configuration Document is available upon request.

Idaho has adopted the pavement performance measures shown in Table 2-2. Measures for IRI and rutting are the same as federal measures. OCI is on a scale of 0 – 100, with 100 representing "perfect" pavements. This index is useful as it allows non-technical consumers of the data a quick and intuitive means to understand overall performance without needing to understand the details of the scores directly.

Table 2-2: Idaho Pavement Measures

Idaho Pavement Measures	
International Roughness Index (IRI)	
<95	Good
96-170	Fair
>171	Poor
Overall Condition Index (OCI)	
>=80	Good
79 - 60	Fair
< 59	Poor
Rutting Asphalt	
<0.2 inches	Good
0.21 - 0.4 inches	Fair
>0.4 inches	Poor

Idaho Performance Target - Pavement

For all other non-NHS routes, ITD retains its existing pavement target that no more than 20 percent of lane miles are in poor condition. ITD will not use as the measure for these Non-NHS pavements the same criteria of Good, Fair, and Poor that it reports for the Federal measures (See Table 2-2). ITD believes that its own long-standing measures provide more insight into the distresses on each pavement, which allows more refined and timely identification of the proper pavement treatment. The non-NHS assets are not officially included in this asset management plan. In order to provide context for the other assets the agency manages, federal regulation allows mentioning these non-NHS assets.

As seen in Figure 2-1, 85 percent of the entire State Highway System (SHS) is in good or fair condition. Because ITD maintains Interstates and Commerce routes to higher levels than all routes statewide, it appears likely that ITD will continue meeting the Federal target. In addition, ITD uses a stricter standard for "poor" pavement than does FHWA. The long-term Idaho trend is for pavements to be generally stable with funding from the past 15-years keeping pavement conditions within a narrow range between 80 and 85 percent in good or fair condition for the entire network.

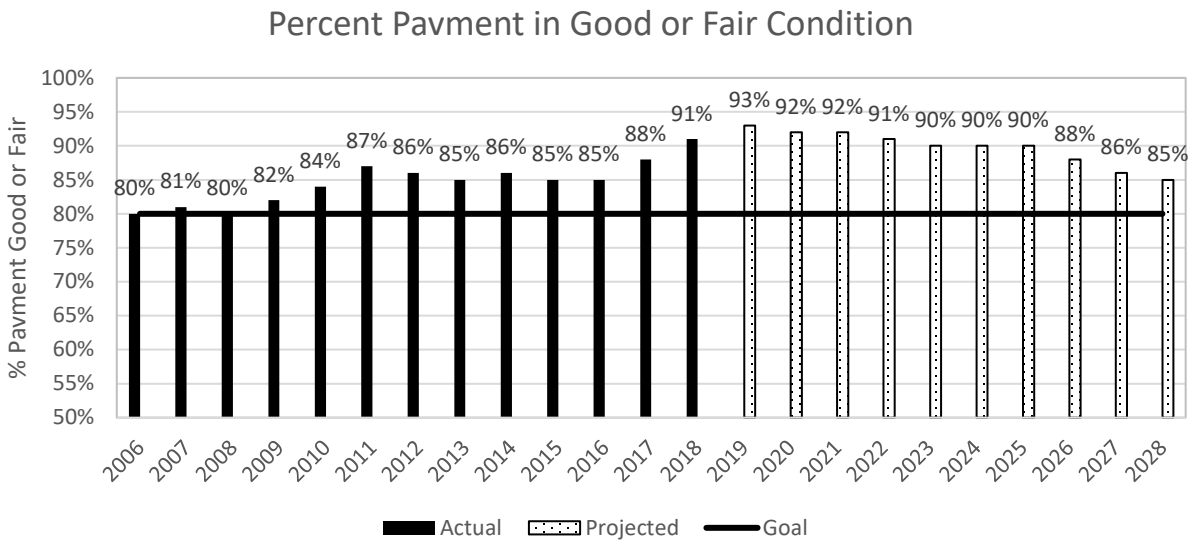

Figure 2-1: 2018 State Highway System (SHS) Pavement Long Term Trend and Forecast (Federal Criteria)

Idaho Performance Measures and Targets – Bridges

Idaho Measures - Bridge

ITD has successfully used a bridge performance measure for over 10 years for the purposes of prioritizing and optimizing the selection of its bridge preservation, rehabilitation, and replacement projects.

The Idaho Performance Measure for Bridges is the square footage of deck area on all State Highway System (SHS) bridges in Good condition. There are several key things to note with this measure. First, ITD defines a bridge as any structure, including culverts, having a span length of 10 feet or greater. Second, using this definition for a bridge, the SHS is composed of currently 1,835 bridges with 12,659,970 square feet of deck area. This is the deck area of all bridges longer than 10 feet on Interstate, U.S. routes, and State Highway routes in Idaho. Finally, ITD evaluates the primary components on each bridge: the deck, superstructure, and substructure, or culvert condition.

- Decks are the horizontal portion of the bridge, usually made of concrete; the deck is atop the superstructure and includes the traffic-carrying surface.
- Bridge superstructure is the portion of the bridge that supports the deck, spans the opening, and connects the substructure elements.
- Bridge substructure is the portions of the bridge including piers and abutments that transfer the load from the superstructure to the foundations.
- Culvert is a buried structure such as a large pipe or box carrying a roadway

ITD evaluates each of these components and assigns a numeric (0-9) scale for each component per the definitions in the National Bridge Inventory (NBI). Each number on the scale corresponds to a condition descriptor, with 9 being a component in excellent or like new condition with no problems. The scale concludes at zero (0) with that component having failed and no longer useable or able to perform its intended function. The full depiction of the 0-9 scale is shown in Figure 2-2.

Figure 2-2: Crosswalk Idaho Bridge Measure to Federal Measure

NBI Rating	0	1	2	3	4	5	6	7	8	9
Description	Failed	Imminent Failure	Critical	Serious	Poor	Fair	Satisfactory	Good	Very Good	Excellent

NOT GOOD GOOD

The lowest component rating for the deck, superstructure, and substructure or culvert sets the overall rating for the bridge. Any bridge with the deck, superstructure, and substructure or culvert all rated six or better is considered "Good" condition. Any bridge with any of these components rated less than satisfactory (six) is considered "Not Good". The total deck area of all bridges in Good condition is summed up and compared to the total deck area for all SHS bridges.

Most recent Idaho Bridge Performance:

Figure 2-3: ITD Dashboard Showing Bridge Condition

Idaho Performance Target - Bridge

The target for the Idaho Bridge Performance Measure is to achieve and maintain at least 80 percent of bridges in "Good" condition (six or better). Again, this is measured by deck area. For calendar year 2018, 75 percent of all of Idaho's bridges on the interstate, U.S. routes and State Highway routes were in Good condition. Later chapters will discuss the 5 percent gap between the current performance and the desired target as well as strategies Idaho is taking to close this gap.

Federal Performance Measures

In 2012, Congress passed the Moving Ahead for Progress in the 21st Century Act, known as MAP-21. That act moved the Federal Highway program towards a performance-based focus. Included in the act were requirements to establish performance measures and to set performance targets. In addition, the act requires states to develop 10-year asset management plans for how they will sustain pavements and bridges in a state of good repair.

FHWA sets some performance measures and it has set two minimum condition levels. One minimum level is that no more than five percent of Interstate Highway pavement lane miles can be in poor condition. Furthermore, no more than 10 percent of NHS bridge deck area can be in poor condition for three consecutive years.

The Federally required performance measures are:

1. Pavements.

- Percentage of Interstate pavements in Good condition
- Percentage of Interstate pavements in Poor condition
- Percentage of pavements on the non-Interstate NHS in Good condition
- Percentage of pavements on non-Interstate NHS in Poor condition.

2. Bridges

- Percentage of NHS bridges in Good condition
- Percentage of NHS bridges in Poor condition

Federal Performance Measure - Pavements

For pavements, FHWA has separate methods for assessing the conditions of asphalt and concrete pavements. For asphalt pavements, it requires measurement by:

- IRI, which is the International Roughness Index, or a measure of how smooth the pavement is. A sophisticated data-collection vehicle determines the amount of "bounce" or roughness per mile.
- Cracking, or the percentage of cracks on each mile of pavement.
- Rutting, or the amount of depression in the wheel path.

For concrete pavements, the metrics differ somewhat because concrete pavements don't rut but they do "fault", which means that the individual slabs rise or fall creating a "bump" between slabs. For concrete pavements, the measures are:

- IRI
- Cracking
- Faulting

Table 2-3 includes the measures and thresholds FHWA uses to determine if pavements are good, fair, or poor. If states have more than 5 percent of their Interstate pavements in poor condition, they must increase investments in Interstate pavements until they reach the five percent level.

Table 2-3: Federal Measures for Asphalt and Concrete Pavements

Asphalt Pavements	
International Roughness Index (IRI)	
<95	Good
96-170	Fair
>171	Poor
Percent Cracking	
<5%	Good
6%-20%	Fair
>20%	Poor
Rutting	
<0.2 inches	Good
0.21 - 0.4 inches	Fair
>0.4 inches	Poor

Concrete Pavements	
International Roughness Index (IRI)	
<95	Good
96-170	Fair
>171	Poor
Percent Cracking	
<5%	Good
6%-15%	Fair
>15%	Poor
Faulting	
<0.1 inches	Good
0.11 – 0.15 inches	Fair
>0.15 inches	Poor

The 2017 ITD HPMS pavement data, Table 2-4, indicate that ITD's interstate pavement conditions are better than the required minimum Federal condition levels. The performance of the non-interstate NHS is slightly below the performance target.

Table 2-4: Idaho Interstate and NHS Pavement Conditions, 2019 HPMS Report

	Percent Good	Percent Fair	Percent Poor
Interstate	65.6	34.2	0.2
Non-Interstate NHS	50.8	48.9	0.3

As seen in Table 2-4 , the amount of poor Interstate pavement conditions could triple and Idaho would remain beneath the federal minimum condition level of no more than five percent poor. The percentage of "Good" NHS pavement is slightly below the ITD target value of 50 percent has chosen. Chapter Four presents further discussion of this performance gap and mitigation strategies. The federal metrics, measures and performance criteria are the basis of these performance measures.

Although ITD has identified the NHS-Local jurisdiction as a sub-asset class and requested that it be excluded from lifecycle planning, ITD acknowledges the importance of collecting data, monitoring the performance, and communicating to the jurisdictional agencies. ITD has and will continue to collect pavement data for this sub-class of assets. Table 2-5 is provided to demonstrate this commitment. Based on 2016 biennial HPMS data, this table shows both the performance of the Local NHS as well as the contribution to the overall SHS NHS performance. In Chapter Three, - Summary Description of Assets, examples

are given of how ITD communicates system performance data.

Table 2-5: 2018 HPMS Local NHS Pavement Performance

NHS-Local	% Good	% Fair	% Poor	Not Collected
NHS-Local	17.1%	42.4%	0.80%	39.7%
Contribution NHS Overall Performance	0.84%	2.08%	0.04%	4.91%

It warrants emphasis that ITD uses the same measures for asphalt and concrete pavements as set forth by federal regulation. ITD will continue to utilize these metrics to report, assess and predict NHS performance. Additionally, ITD has well established processes for pavement data collection that, for the near future, supports collection of pavement performance data to this end. That said, ITD utilizes accepted internal metrics, measures and reporting criteria for system performance monitoring, and lifecycle planning. These measures are compared to the federal criteria and are shown in Table 2-6 on page 2-10.

Federal Performance Target – Pavement

For this asset management plan, ITD sets the following pavement targets:

Target for Interstate pavements:

For Interstate Highway System pavement, the target is that no more than four percent of lane miles will be in poor condition, with poor defined as per the Federal measure of two or more distresses in the poor category. This gives ITD significant cushion to have Interstate conditions deteriorate and still be within the Federal target. For the percentage of good pavements, ITD adopts an Interstate Highway target of 50 percent.

Target for NHS pavements:

For NHS pavement, the target is that no more than eight percent of NHS lane miles will be in poor condition as per the Federal measures of two or more distresses in the poor category and that 50 percent be in good condition.

Federal Performance Measure - Bridge

For the Federally required asset management plan and performance reporting, ITD follows the criteria set by the FHWA for determining if bridges are in good, fair, or poor condition. The Federal Performance Measure is similar to the Idaho Performance Measure, but also has a couple of notable differences:

- A bridge is any structure, including culverts, having a span length of greater than 20 feet.
- Only those bridges on the National Highway System (NHS) are considered for this measure. In Idaho, there are 870 bridges with 8,816,021 square feet of deck area on the NHS.

Similar to the Idaho Performance Measure for Bridges, the Federal Performance Measure evaluates the

same four primary bridge components; the deck, superstructure, and substructure, or culvert condition using the same numeric (0-9) condition scale described previously. The lowest condition of any of the four components, determines whether the overall bridge condition is good, fair, or poor.

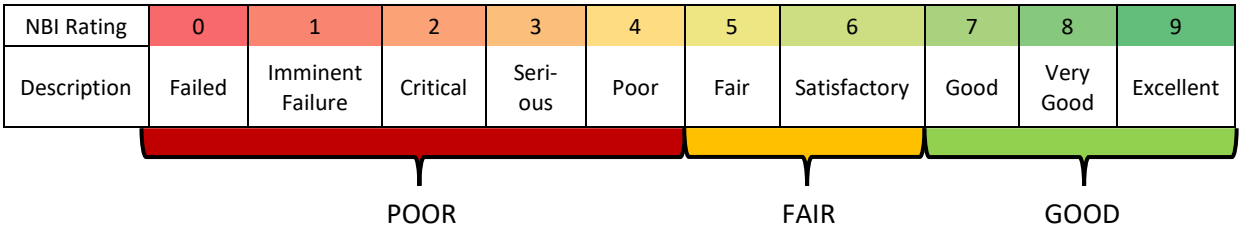

Figure 2-4: Federal Bridge Performance Measures

The total deck area of all bridges in Good condition and Poor condition are summed up and compared to the total deck area for all NHS bridges.

For Calendar Year 2018, the current conditions of all NHS bridges in Idaho are shown in Figure 2-5:

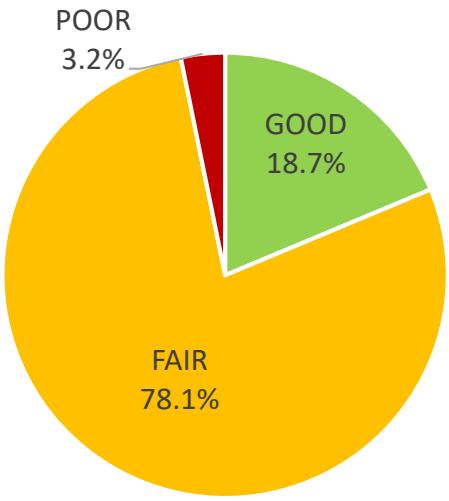

Figure 2-5: 2018 NHS Bridge Conditions

Federal Performance Target - Bridge

The target for the Federal Bridge Performance Measure is to achieve and maintain at least 19 percent of NHS bridges in Good condition and no more than three percent of NHS bridges in Poor condition. Again, this is measured by deck area. For calendar year 2018, 18.7 percent of all of Idaho's NHS bridges were in Good condition and 3.2 percent of NHS bridges were in Poor condition. There is a 0.3 percent gap in Good Condition and a 0.2 percent gap for Poor condition between the current performance and the desired targets. While these gaps are small, later chapters will discuss strategies Idaho is taking to close these gaps.

Comparing the Idaho and Federal Performance Measures

Pavements

With respect to pavement condition reporting Idaho's determination of good, fair or poor is different from the federal measure. The federal measure is new and based upon criteria of roughness, rutting, faulting, and percent cracking. The basis for determining roughness and rutting condition are the same between ITD and the federal measures. For example for pavement cracking, ITD measures the same pavement distresses but compiles them into a different index, the Overall Condition Index or OCI. ITD emphasizes that this measure is consistent with ITD internal reporting purposes only: supplanting the federal crack measure is not the intent. The most fundamental difference lies not with the measures, but rather with the way measures are utilized to assign the performance condition. As shown in Table 2-6, the difference between ITD performance criteria to federal criteria is that the lowest measure (roughness, OCI, rutting) determines the pavement section overall performance. This is analogous to the so-called, three leg stool model, which means that the stool will lean in the direction of the lowest of the three legs. Federal performance is much more liberal in that it requires two of the three criteria to be poor for the section to be rated as poor. More specifically, the federal performance criteria require all three measures must be good to be classified as good condition; poor condition requires two measures to be poor. Everything else is fair condition.

Table 2-6: Pavement Measures and Condition Crosswalk Table

FHWA	ITD
Performance Measures:	
International Roughness Index (IRI) Percent Cracking (Asphalt or Concrete) Rutting (Asphalt Only) Faulting Concrete (Concrete Only)	International Roughness Index (IRI) Overall Condition Index (OCI)* Rutting (Asphalt Only)
Performance Criteria:	
All performance measures "Good" = "Good" Two Performance measures "Poor" = "Poor" All other combinations = "Fair"	Lowest of performance measures determines pavement performance.
*The Overall Condition Index is a composite index (0-100) based on structural and non-structural pavement distresses determined by the manifestation of various crack types. Good: OCI >80; Fair: OCI Between or equal to 60 & 80; Poor: OCI<60. A complete discussion on the computation and use of OCI is contained in the most current version of the "Pavement Management System Engineering Configuration Document "maintained by ITD Asset Management.	

ITD reviewed past performance of the interstate and non-NHS assets, according to the federal criteria, to establish the pavement performance targets. For all criteria reviewed, there is a difference between the FHWA value and the ITD value. This is the manifestation of the difference in approach to performance criteria given in Table 2-6. Figure 2-6 through Figure 2-9 show this data.

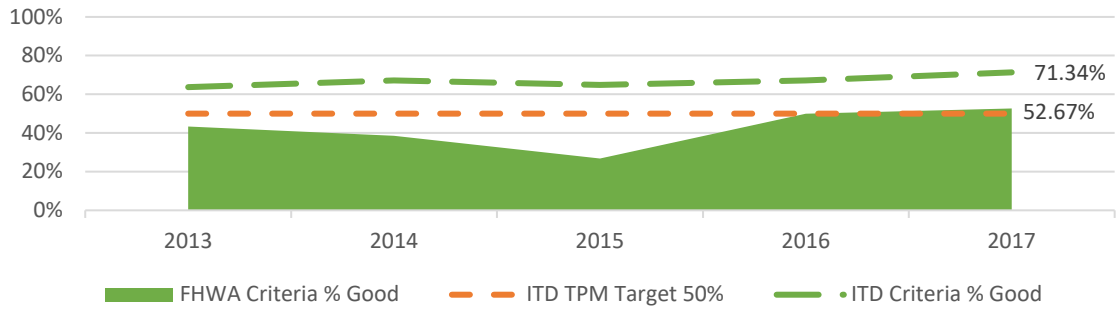

Figure 2-6: Percentage Good Interstate Pavement Performance Crosswalk

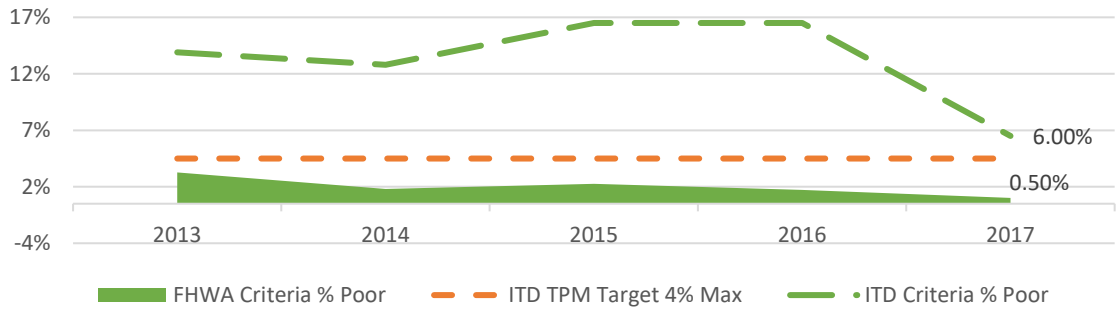

Figure 2-7: Percentage Poor Interstate Pavement Performance Crosswalk

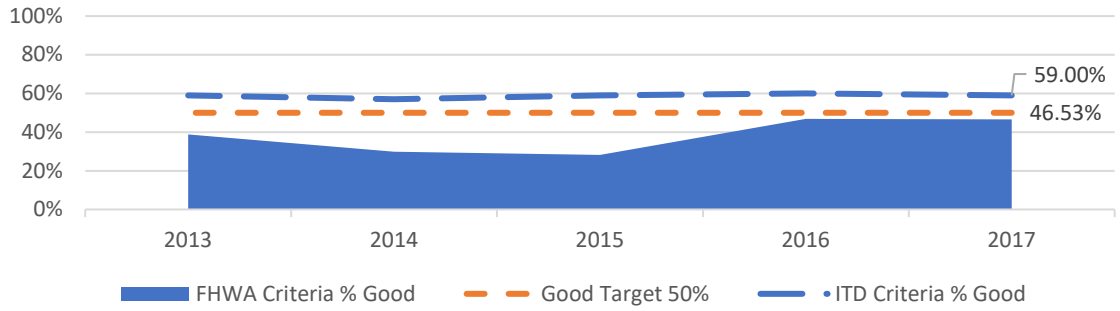

Figure 2-8: Percentage Good Non-Interstate NHS Pavement Performance Crosswalk

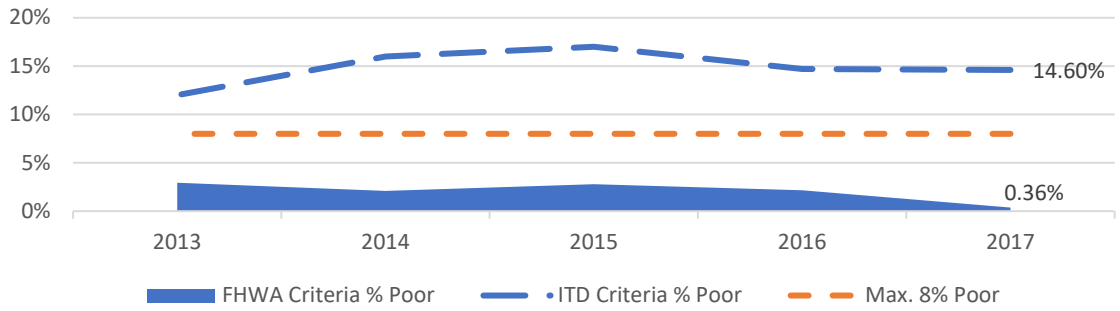

Figure 2-9: Percentage Poor Non-Interstate NHS Pavement Performance Crosswalk

This difference between how ITD measures pavements and the new Federal measure is common among almost all states. States developed their individual means to measure pavement conditions independently years before FHWA developed its standard, nationwide measures. ITD has invested significant resources to be able to use the new federal pavement condition measures as part of ITD's pavement model. The pavement condition data shown in Figure 2-1: 2018 State Highway System (SHS) Pavement Long Term Trend and Forecast are based upon the federal performance criteria. Preliminary indications are that ITD will continue to meet the Federal Interstate and NHS pavement condition targets through the 10- years of the asset management plan. ITD understands that a 10-year performance forecast is required however, as Figure 2-1 shows only a five-year forecast is given.

Bridge

When comparing the Idaho and Federal Performance Measures it is important to note that the Idaho Performance Measure distinguishes between "Not Good" and "Good" whereas the Federal Performance Measure uses three striations, "Poor", "Fair" and "Good". ITD utilizes this approach, as it is simpler and is particularly helpful when talking with the public and our Idaho State Legislature. Table 2-7 presents a crosswalk between the Idaho and Federal Performance Measures.

Table 2-7: Comparison between Idaho and Federal Performance Measures

<table>
<tr><th>Rating</th><th>Condition</th><th>Idaho Performance Measure</th><th>Federal Performance Measure</th></tr>
<tr><td>0</td><td>Failed</td><td rowspan="5">"Not Good"</td><td rowspan="4">Poor</td></tr>
<tr><td>1</td><td>Imminent Failure</td></tr>
<tr><td>2</td><td>Critical</td></tr>
<tr><td>3</td><td>Serious</td></tr>
<tr><td>4</td><td>Poor</td></tr>
<tr><td>5</td><td>Fair</td><td rowspan="4">"Good"</td><td rowspan="2">Fair</td></tr>
<tr><td>6</td><td>Satisfactory</td></tr>
<tr><td>7</td><td>Good</td><td rowspan="3">Good</td></tr>
<tr><td>8</td><td>Very Good</td></tr>
<tr><td>9</td><td>Excellent</td></tr>
</table>

Conclusion

ITD uses the FHWA performance measures as its measures for the asset management plan and for the required FHWA performance reporting. ITD has set two and four year targets as shown in Table 2-8.

Table 2-8: Performance Measures and Targets Crosswalk

Performance Measure	Federal Measure	Federal 2 & 4 Year Targets	ITD Measure	ITD 2 & 4 Year Targets
Pavement	Interstate NHS Percent Good	50%	SHS Percent Good or Fair	80%
	Interstate NHS Percent Poor	4%		
	Non-Interstate NHS Percent Good	50%		
	Non-Interstate NHS Percent Poor	8%		
Bridge	NHS Bridge Percent Good	19%	SHS Bridges Percent Good	80%
	NHS Bridge Percent Poor	3%		

Chapter 3 - Summary Description of Assets

Background

ITD manages a diverse highway network that serves the rapidly growing Boise area, mountainous tourist areas such as Coeur d'Alene, near-desert climates, and sprawling regions stretching from northern Utah to the Canadian border.

ITD's transportation inventory reflects the geology, geography, and economy of the state. Idaho is a relatively large, lightly populated state with a growing population. It is the nation's 14th largest in terms of area with 83,569 square miles.[i] Its 2016 estimated population of 1.68 million is the nation's 13th smallest. Idaho's population grew by 115,558 between 2010 and 2016, the 10th fastest growing state in the nation.[ii] However, the growth is concentrated with 83 percent of it occurring in three counties, Ada, Canyon, and Kootenai. Ada and Canyon counties include the metropolitan Boise area while Kootenai County includes Coeur d'Alene. Twenty counties lost population between 2010 and 2016, while another 16 grew by less than 1,000 people over five years.[iii]

Figure 3-1: The I. B. Perrine Bridge, US 93, over the Snake River Canyon, Twin Falls, Idaho

A snapshot of the state's population and economy shows a lightly populated state with a diverse economy. Boise is by far the state's largest city with 218,281 people, more than twice the size of the next largest which are Meridian and Nampa with both around 90,000 people. Idaho's unemployment rate is low with a February 2018 unemployment rate of 2.9 percent. However, it has the 15th lowest annual household income of $47,583 per year.[iv] A list of Idaho's 35 largest private employers is dominated by hospitals and retailers but also includes Micron manufacturing, Battelle Energy Alliance, Bechtel Marine Propulsion, and several manufacturers employing more than 1,000 people.[v] Tourism also is a large sector in Idaho employing an estimated 2,800 people and contributing about $500 million in direct payroll.[vi]

Commodities are a significant portion of the Idaho economy and create demand for heavy trucks. Forestry and timbering contributed to Idaho's economy about $2.6 billion in 2014 in direct sales.[vii] The mining and oil industries employ about 3,200 workers with a payroll of about $278 million in 2012.[viii] In addition,

agriculture is a major employer with an average annual labor force of nearly 52,000 people.[ix] The commodity-driven industries of agriculture, mining, oil, and timbering contribute to demand for heavier loads. ITD has a process for approving 129,000-pound loads on certain routes and sections so that trucks can carry more than the normal 80,000-pound limit.

ITD manages a State Highway System (SHS) of approximately 5,000 centerline miles, or over 12,000 lane miles, plus more than 1,800 bridges. The entire Idaho Transportation Network is more than 60,000 miles with local governments owning the large majority. ITD's routes carry 54 percent of the state vehicle miles of travel (VMT) with 45 percent of the state's VMT being on the Interstate Highway System network. Within Idaho there are more than 4,000 bridges, of these 1,835 bridges are managed by ITD. There are 807 State Highway System bridges and culverts greater than 20-foot in length on the NHS (with an area of 8,148,547 sq. ft.). There are 63 local bridges and culverts (with an area of 667,474 sq. ft.) on the NHS, all these structures are greater than 20-feet in length.

Figure 3-2: US 93 in Idaho, One of the Many Rural Roads so Important in the State.

ITD Asset Classes

An integral part to ITD being effective in life cycle planning, and by association, asset management, is segregating our assets in to different classes. This enables ITD to tailor and prioritize the life cycle cost processes based on performance indicators defined for each asset class.

ITD recognizes the following asset classes within the Idaho Transportation Network:

- State Highway System (SHS)
- Local (non-SHS) roads
- National Highway System (NHS)
- State Highways
- NHS Bridges
- NHS Local Bridges
- Non-NHS Bridges

Sub-Asset Classes recognized are:

- Interstate

- State Jurisdictional NHS
- Local Jurisdictional NHS
- Commerce Routes
- Non-Commerce Routes.
- Rigid Pavements
- Flexible Pavements

Figure 3-3 presents graphical representation of this taxonomy.

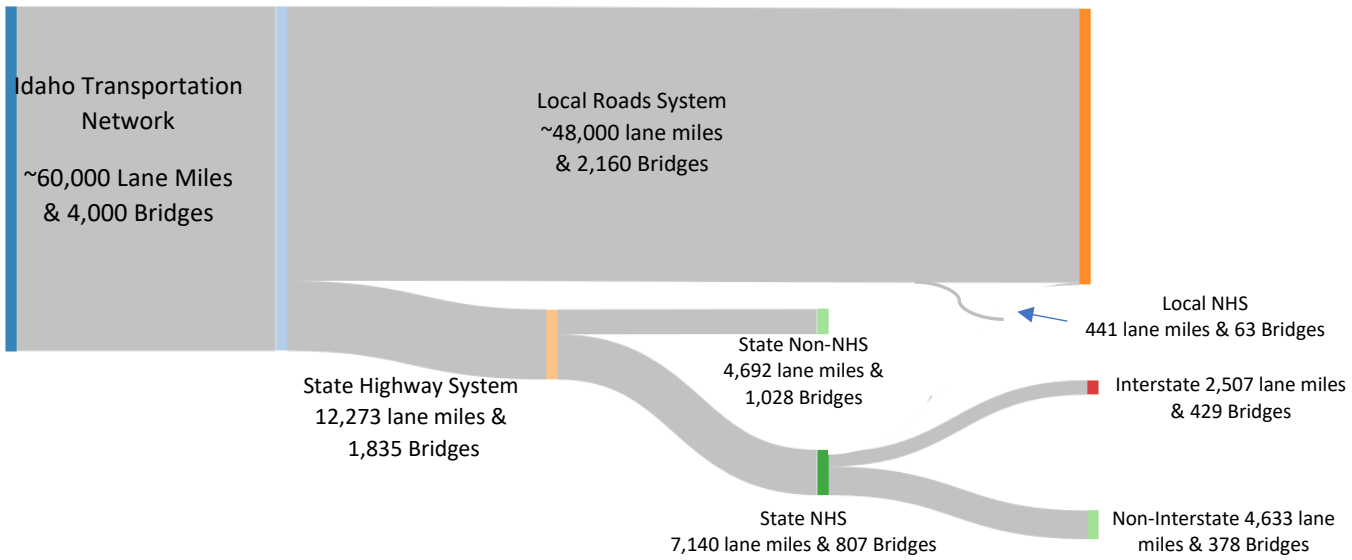

Figure 3-3: Idaho Transportation Network Asset Classes

The Figure 3-4 summarizes the distribution of lane miles based on the asset classes recognized by ITD. As shown in Figure 3-4, the majority of the State Highway System, 62 percent, is comprised of National Highway System (NHS) facilities. Non-Interstate roadways comprise two-thirds of the Idaho NHS system. With respect to bridges, Figure 3-5 shows the distribution of total deck area and highlights that 47 percent of the total deck area is located on the NHS, with just four percent of that belonging to local jurisdictions. Provided in Appendix A is a complete listing of the assets by asset class.

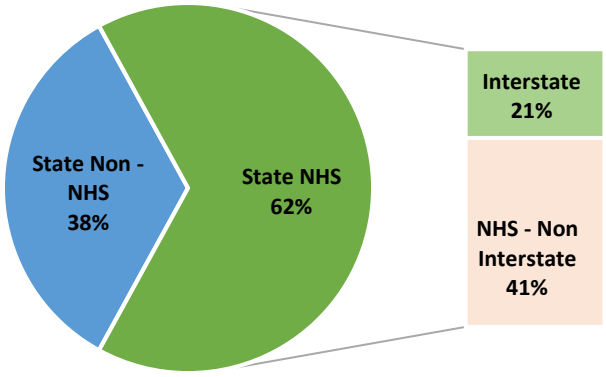

Figure 3-4: SHS Lane Miles Distribution

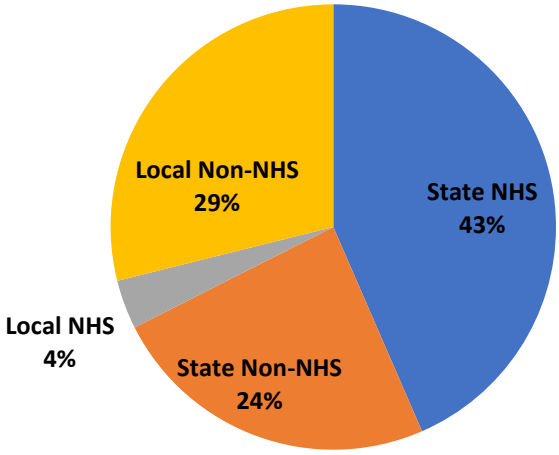

Figure 3-5: Distribution of Total Deck Area in Idaho

ITD also recognizes sub-asset classes within the SHS, commerce and non-commerce routes. Beginning in 2015, ITD divided the highway network into Commerce and Non-Commerce Routes for prioritization. Commerce Routes have more than 300 commercial trucks per day, while routes with fewer trucks are non-commerce routes, (See Figure 3-6). This stratification closely aligns with the ITD portion of the NHS and allows ITD to prioritize its resources where there is the most commerce, the greatest axle loadings, and generally the economic activity.

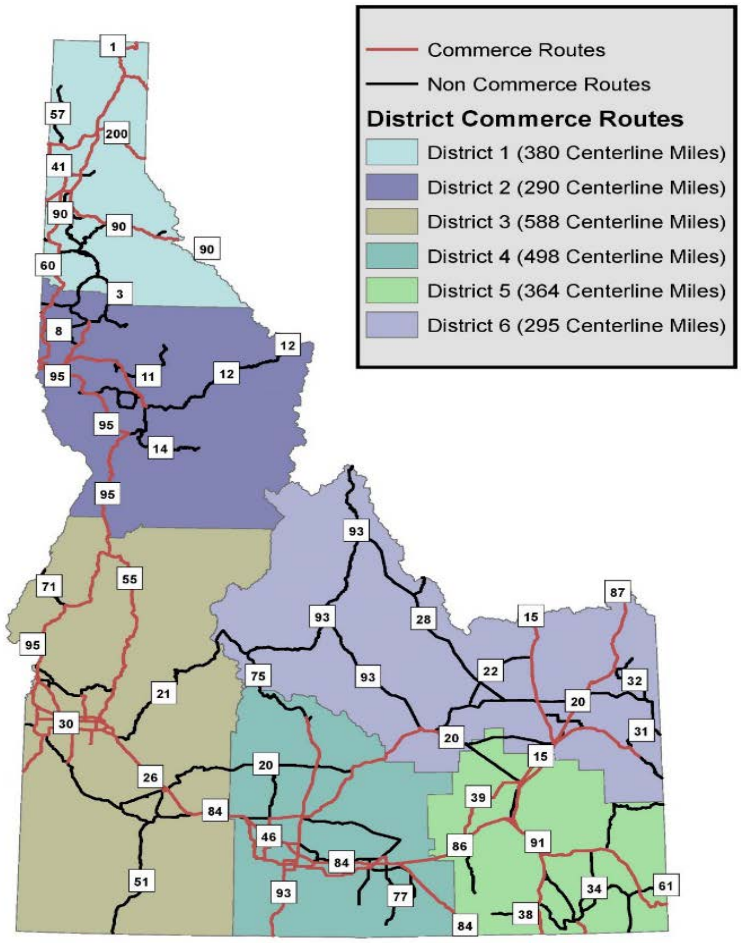

Figure 3-6: Map of Idaho Commerce Routes

Pavements

Condition and Trends

Since 1998, ITD has published an annual pavement condition trends report. It also produces a web-based performance dashboard that summarizes performance and targets for pavements, bridges, safety, and other performance areas. These reports make the ITD condition trends transparent. As seen in Figure 3-7, pavement conditions generally have improved, and statewide conditions remain above the ITD target of 80 percent of pavements in "Good" or "Fair" condition. As discussed in Chapter 2, this chart is based on the ITD defined performance criteria.

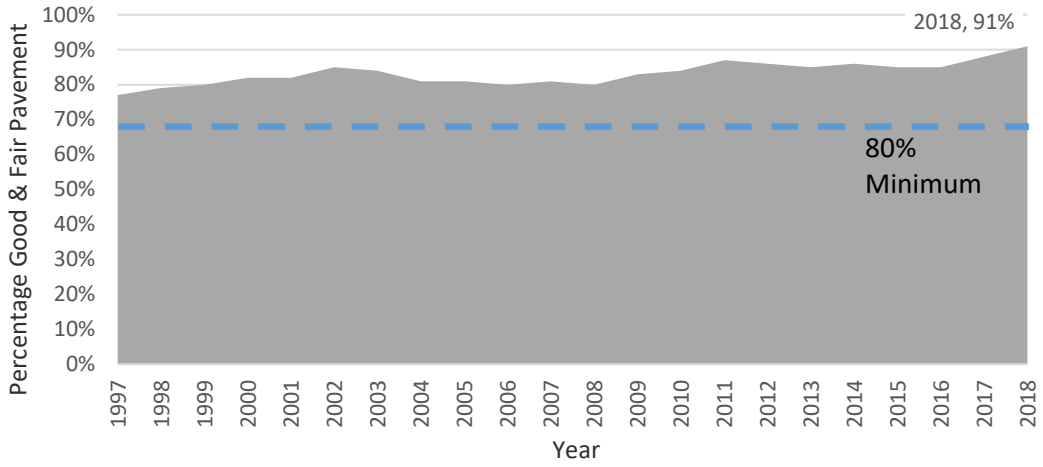

Figure 3-7: Idaho SHS Pavement Condition Trends (ITD Criteria).

For ITD's highest functional class, the Interstate Highway System, ITD's conditions are very good. According to the pavement data ITD reported to the Highway Performance Management System, 52.67 percent of the 2,530 Interstate lane miles are in good condition, 46.83 percent are fair and only 0.50 percent are poor. For the National Highway System (non-Interstate) as of 2017, out of 5,396 lane miles, 46.53 percent are good, 53.10 percent are fair, and 0.36 percent is poor.

Another aspect of pavement condition performance that is important to review is how the statewide pavement conditions are changing year over year. For instance, it would be very telling to see large changes between good and fair pavement in a given year, which is indicative that large portions of the network are deteriorating at the same time. ITD asset management has an established process to monitor year over year changes in performance. Figure 3-8 through Figure 3-10: NHS Non-Interstate Pavement Performance Percent Change 2015-2018 (MAP-21 Criteria) show the percentage change between 2015 thought 2018 within the NHS. These charts show that there has been a reduction in "Good" to "Fair" pavements as computed according to the MAP-21 Criteria.

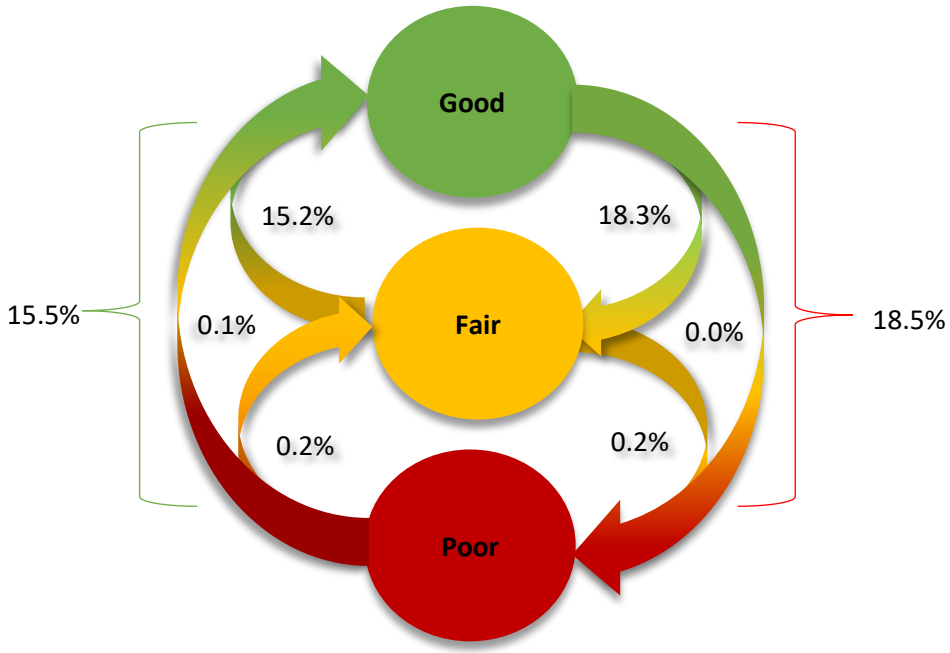

Figure 3-8: NHS Pavement Performance Percent Change 2015-2018 (MAP-21 Criteria)

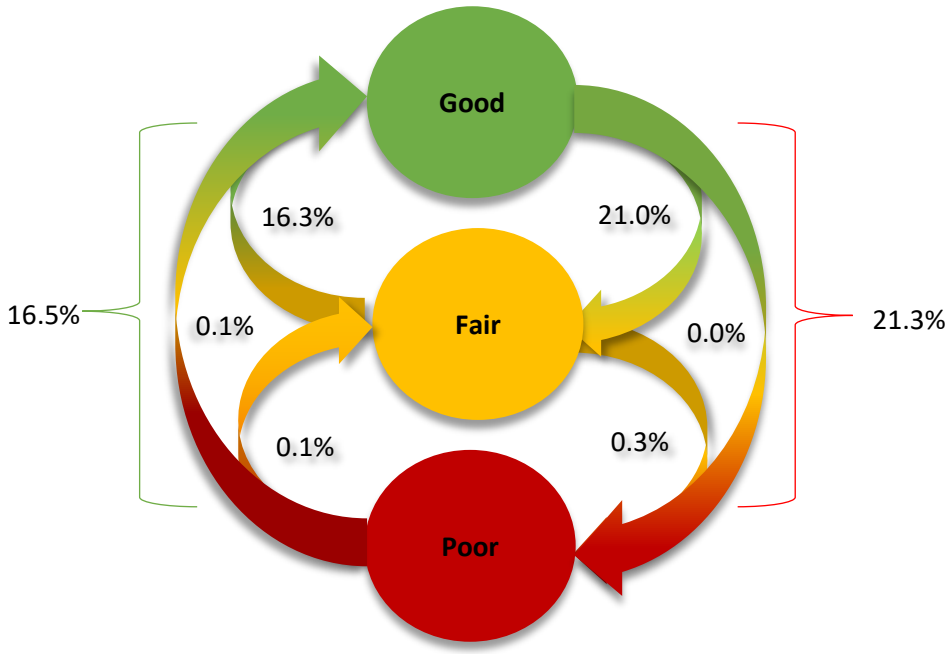

Figure 3-9: NHS Interstate Pavement Performance Percent Change 2015-2018 (MAP-21 Criteria)

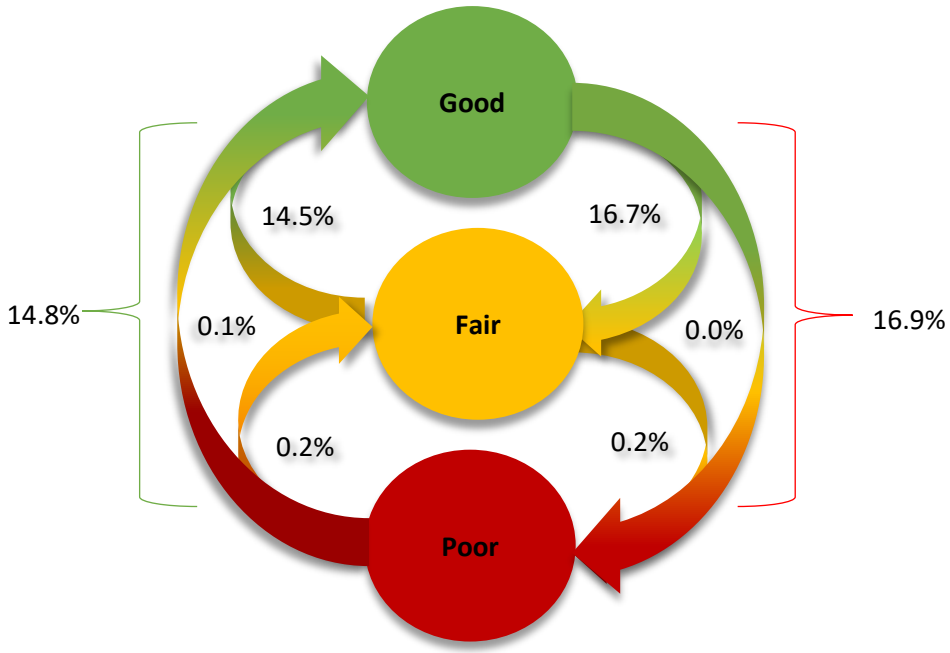

Figure 3-10: NHS Non-Interstate Pavement Performance Percent Change 2015-2018 (MAP-21 Criteria)

In order to obtain a holistic view of statewide pavement performance, results are further reported out by ITD District. The intent is not to highlight or compare one District to another, rather it is to ensure that there is uniformity across the State and that budget distributions reflect not only the overall need of the State but align with the needs of each District, as shown in

Figure 3-11. ITD has also incorporated the use of geographic information system (GIS) to provide District specific maps showing pavement performance (See Figure 3-12.)

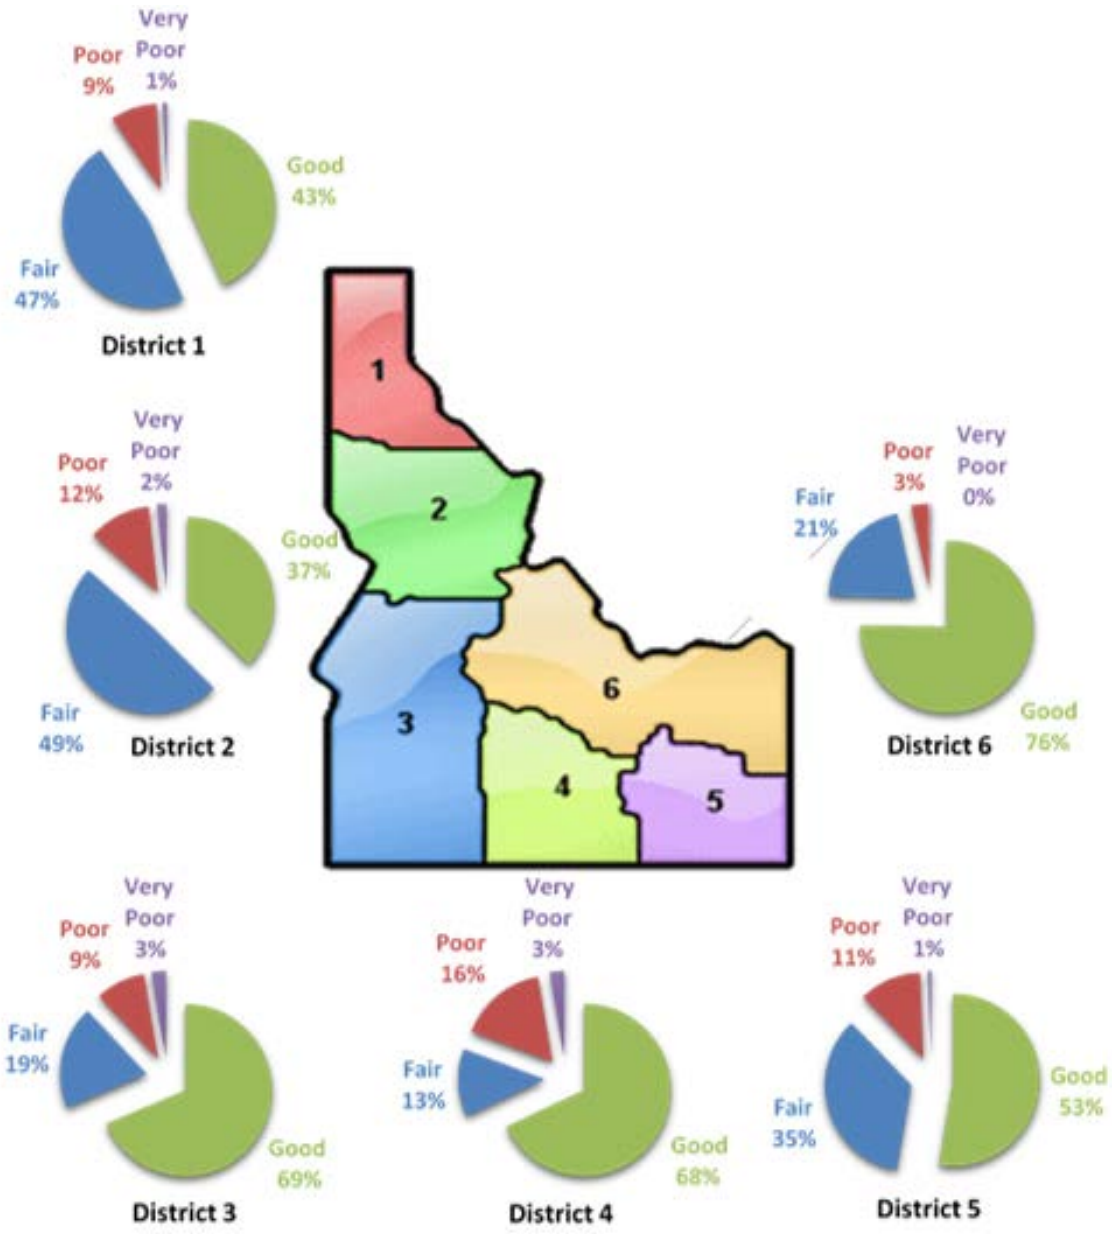

Figure 3-11: Overview of State Highway System Pavement Performance by District (ITD Criteria)

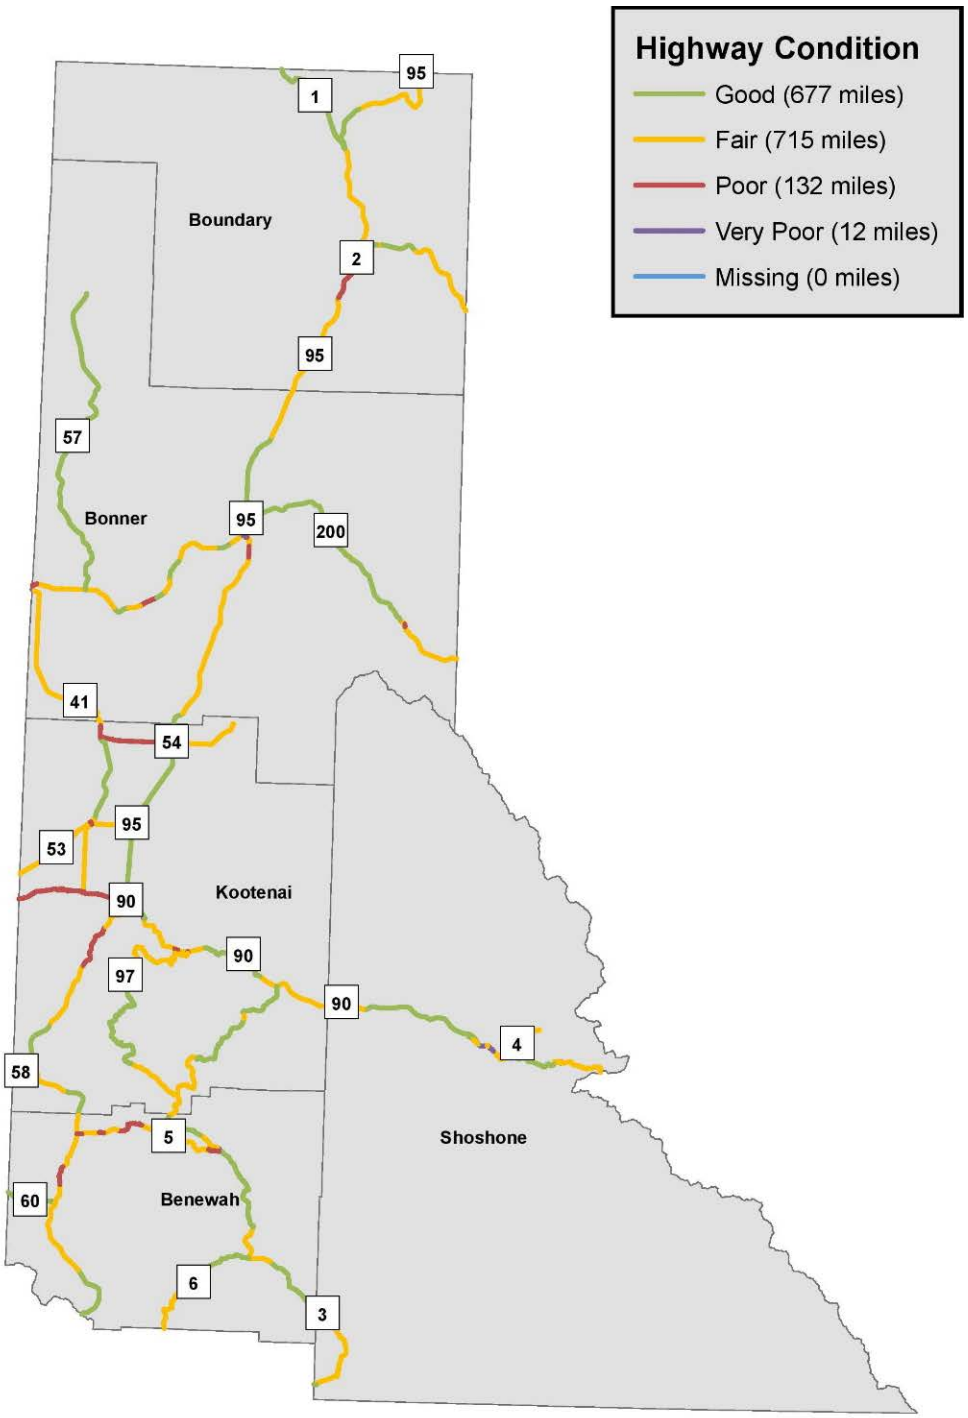

Figure 3-12: Example of GIS Map to Report Pavement Conditions (ITD Criteria)

Measurement and Management Process

ITD uses a more stringent performance standard for assessing pavement condition. The reader is referred to Table 2-6: Pavement Measures and Condition Crosswalk Table on page 2-10. The intent of the ITD performance standard is to identify and mitigate deficient pavements well in advance of the national performance standard set by FHWA. This section describes the history, process, measures, and results of ITD's pavement management process.

Over the years, ITD has updated the pavement management and pavement-selection processes. In 1978, it acquired a mainframe Pavement Management System (PMS) and by 1986, it was using the system to perform simplistic economic analysis and optimization. In 2007, it shifted to the Highway Economic Requirements System State model (HERS-ST). In 2009, it purchased a commercial pavement and Maintenance Management System (MMS). The PMS includes inventories, calibrated deterioration curves, decision trees, performance models, and an optimization analysis engine.

ITD uses the current system at a network level to indicate how much should be invested in pavements to achieve the department's target, and how the funds should be split between preservation and rehabilitation or replacement. The system is not used at the project level. The network analysis is broken down by district, and the analysis used to allocate funds to the districts.

Once districts receive their pavement allocations, they identify projects based partially on the PMS information. Often, district engineers pick projects based upon local conditions, pavement condition reports, their own judgment, and local political input. ITD has pavement-design manuals, which help material engineers design treatments to maximize the pavement's lifecycle performance. The analyses have led to many pavement rehabilitation projects on the higher-volume Interstates to achieve a good life-cycle result. In addition, the districts have a preservation budget to work with which they also can use to improve the life-cycle performance of pavements.

The district-identified pavement projects are directly uploaded into the pavement management system and ITD runs the projects in the PMS analysis engine. The analysis uses the deterioration curves and programmed projects to calculate how the program will benefit the pavement network.

The extent of ITD's pavement data collection and analysis allow staff to analyze pavement conditions from many perspectives to assess overall performance. ITD is not only concerned about pavement smoothness but this process also analyzes rutting which, when excessive, can contribute to crashes because of water laying in the wheel path depressions. Cracking can also be analyzed to determine what types of treatments a pavement requires, or how long a pavement will perform. ITD provides substantial pavement distress data to its districts for them to analyze their pavement conditions and needed treatments. Examples of this data, based on the FHWA measures, are shown in Figure 3-13 through Figure 3-16. These figures show the percentage of good, fair, poor as well as three year average of the data.

Historically, the PMS used thresholds in the cracking index and roughness index to determine whether or not a pavement is Good, Fair, "Poor" or "Very Poor". These thresholds were triggered by two tiers of thresholds, based on the functional class of a roadway:

- Tier 1: Interstates and arterials
- Tier 2: Collectors

Districts would use the "Poor" or "Very Poor" threshold notification to realize that a roadway was ready for a structural project. Through 2009, what was called the Classic Methodology employed only two measurements to determine performance rating: the cracking index and roughness index. In 2010, an improved Profiler van technology and the new PMS system led to the addition of a third measurement to determine pavement performance and rutting depth. Rutting depth was first applied in 2010 as a method to rate pavements. Utilizing three criteria to determine performance is often referred to as the "3-legged stool" model. The analogy is that if one leg of a 3-legged stool is broken, then the stool will not stand. Likewise, if any one of the three criteria that determines pavement performance is "Poor" or "Very Poor" is then the roadway is classified as "Poor" or "Very Poor" irrespective of the other two indices.

ITD vs. Federal Pavement Measurement

The ITD standard of considering a pavement to be rated as "Poor" if one criteria is poor is more stringent than the Federal standard. FHWA regulation considers a pavement to be poor only if it is poor in two of the three criteria. Although ITD uses its own tried and true criteria for measuring its pavements and qualifying pavement performance and conditions, when ITD measures its pavements by the Federal standards it shows very little poor pavement. Table 2-4 shows that when measured by the Federal criteria, only 0.6 percent of the 2018 State Highway System was in what FHWA could classify as poor condition. By the Federal measure, 52.8 percent was good in 2018 and 46.7 percent was fair.

Although ITD reports the pavement data to FHWA to satisfy the Federal regulations, ITD also utilizes this information to monitor the different aspects of pavement performance. Examples of these charts are provided on the following pages. ITD will continue using its performance criteria for reporting pavement performance to its Board, the public, and to its District Offices. ITD believes that its criteria better supports pavement-selection decisions.

	2015 SHS	2016 SHS	2017 SHS	2016 HPMS: Interstate	2016 HPMS: Non-Interstate	Projected 2017 HPMS - Interstate	Projected 2017 HPMS - Non-Interstate
% Good	54.9%	50.8%	50.9%	49.9%	46.8%	52.0%	47.0%
% Fair	44.8%	48.8%	48.6%	48.9%	51.0%	47.0%	52.0%
% Poor	0.3%	0.4%	0.5%	1.2%	2.2%	1.0%	1.0%

Figure 3-16: National Highway System Cracking Percentage

Bridge

There are 4,283 bridges within the State of Idaho owned by State and local governments. These include bridges that are greater than 10 feet in length on the State system and greater than 20 feet in length on the Local system. A description of bridge assets, their conditions and trends will be presented in a similar manner as the performance measures and targets presented in Chapter 2. For the Idaho Bridge Performance Measure, bridge data for the State Highway System (SHS) will be presented. For the Federal Bridge Performance Measure, bridge data for the National Highway System (NHS) will be presented.

Idaho SHS Description of Assets

ITD owns and manages the State Highway System (SHS) in the State of Idaho. The SHS includes all interstate, U.S. and State Highway routes in the State of Idaho. On all of these routes, there are 1,835 bridges greater than 10 feet in length and they comprise 12,659,970 square feet of deck area, seen in Figure 3-17 and Table 3-1. Idaho's Bridge Performance Measure as presented in Chapter 2 includes all of the SHS bridges in that measure.

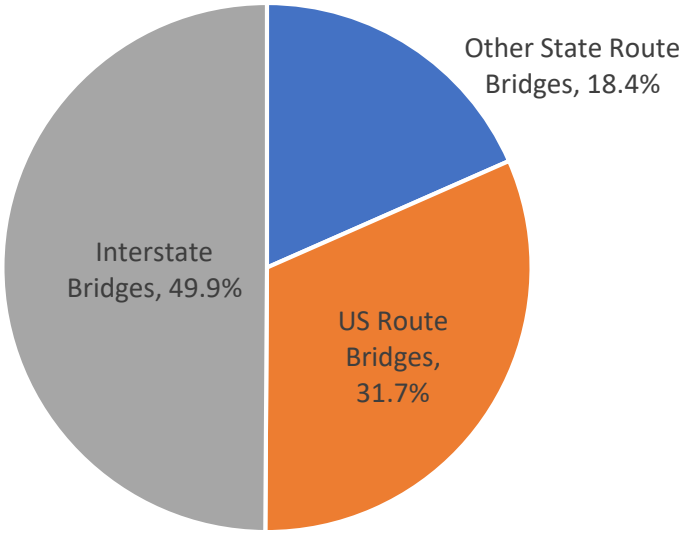

Figure 3-17: SHS Bridge Distribution

Table 3-1: SHS Bridge Distribution

SHS Bridges*	Count	Deck Area
Interstate Bridges	711	6,320,395 sq. ft.
US Route Bridges	571	4,006,997 sq. ft.
Other State Route Bridges	553	2,332,578 sq. ft.
Total State Highway System (SHS) Bridges	**1835**	**12,659,970 sq. ft.**
**Includes bridges with spans between 10' to 20'*		

Idaho SHS Conditions and Trends

75 percent of Idaho's SHS bridges are in good condition. This is based on 9,491,272 of 12,659,970 square feet of deck area being rated satisfactory (6) or better according to the NBI 0-9 scale. A breakdown of the SHS bridge assets in Good and Not Good condition is provided in the following chart.

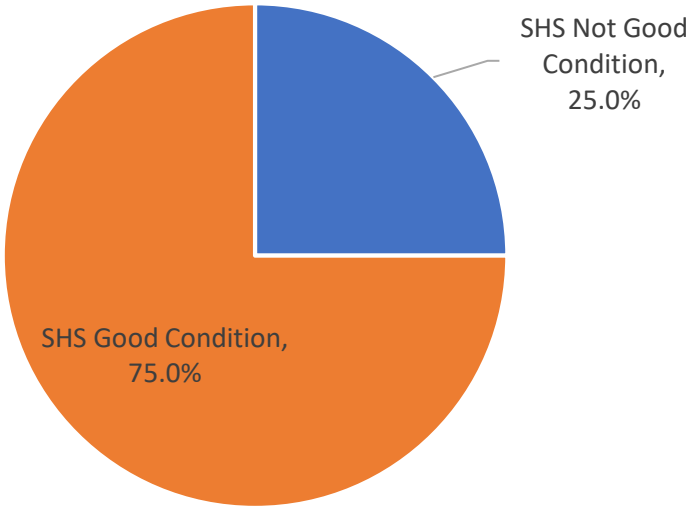

Figure 3-18: SHS Bridge Condition Distribution

A tabular breakdown of Idaho's SHS bridge assets by Good and Not Good condition is shown in Table 3-2.

Table 3-2: SHS Bridge Condition Summary

	NBI Rating	# of Bridges	Deck Area (SqFt)	Deck Area (SqFt) Percent	
Not Good	0	1	6,248	<0.0	25%
	1	0	0	0.0	
	2	1	631	<0.0	
	3	10	84,512	0.7	
	4	62	414,956	3.3	
	5	329	2,662,350	21.0	
Good	6	984	6,722,216	53.1	75%
	7	330	2,227,025	17.6	
	8	71	375,991,	3.0	
	9	47	166,041	1.3	
	Total	**1835**	**12,659,970**	**100**	

As shown in Figure 3-18 and Table 3-2, 75 percent (by deck area) of Idaho's SHS bridge assets are in good condition. Approximately 25 percent of the SHS bridge assets are in "Not Good" condition. Often, these "Not Good" bridges are some of Idaho's oldest bridge assets and are ones that have the lowest strength

capacities or have been designated bridges that restrict commercial truck traffic. Bridge age and restrictions to freight/truck traffic are important factors to ITD as it manages the SHS bridges. While there are not performance measures and targets associated with these, they are important factors used to prioritize and manage our assets. In 2015, there were 112 Commerce Restricted Bridges on the State Highway System. This restriction primarily was due to an antiquated design truck used when the bridges were designed. About 74 of these bridges have been replaced or are in our ITIP scheduled for replacement.

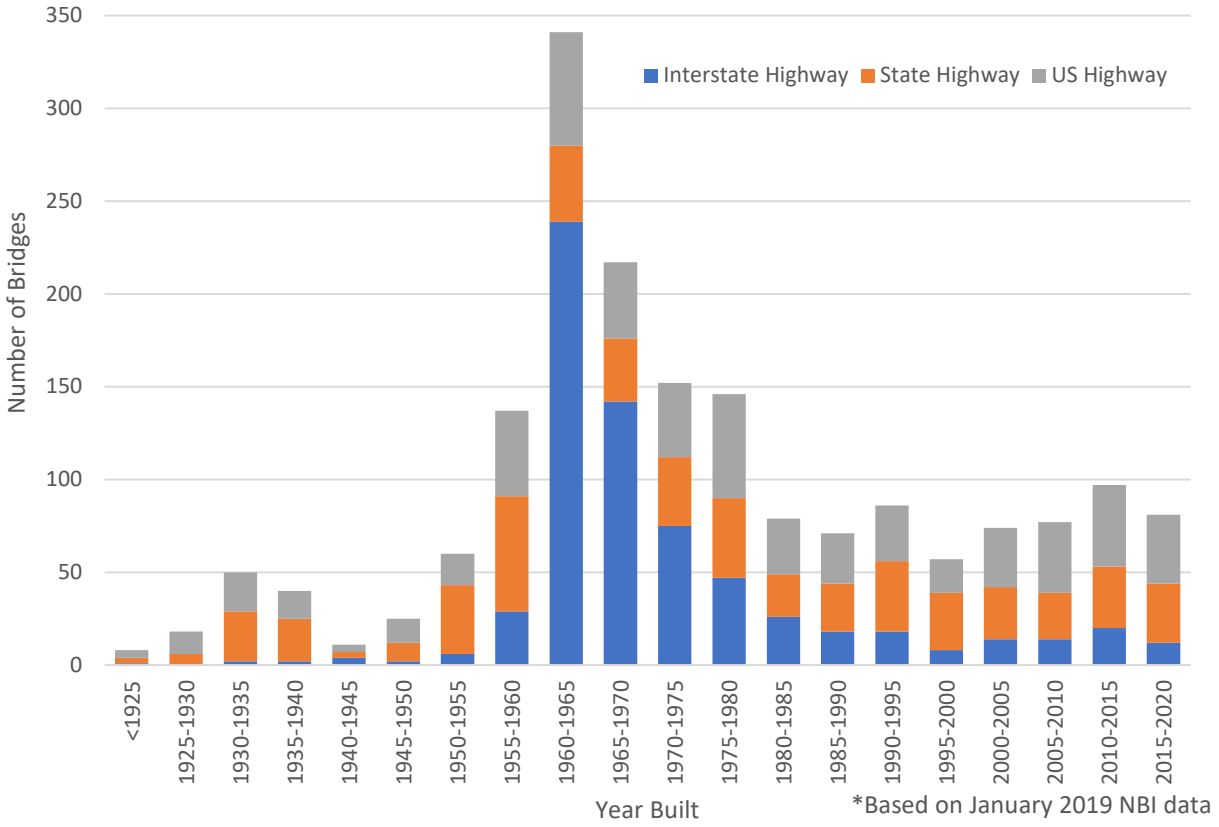

Figure 3-19: SHS Bridge Age Histogram

Using our Bridge Management system, ITD monitors not only the current performance of the SHS Bridge assets but also how that performance is changing over many years. Figure 3-20 shows the past 10 years of SHS performance and the forecasted or predicted next 10 years of bridge condition on the SHS. As you can see, ITD is striving to raise the percentage of SHS bridge assets in good condition to 80 percent. Currently Idaho's SHS bridges are at 75 percent good condition. As stated in Chapter 2, based on current funding levels, ITD is predicting to reach its target for SHS bridge performance in about calendar year 2023. This assumes current funding levels remain in-place and no significant unexpected events/damage occur.

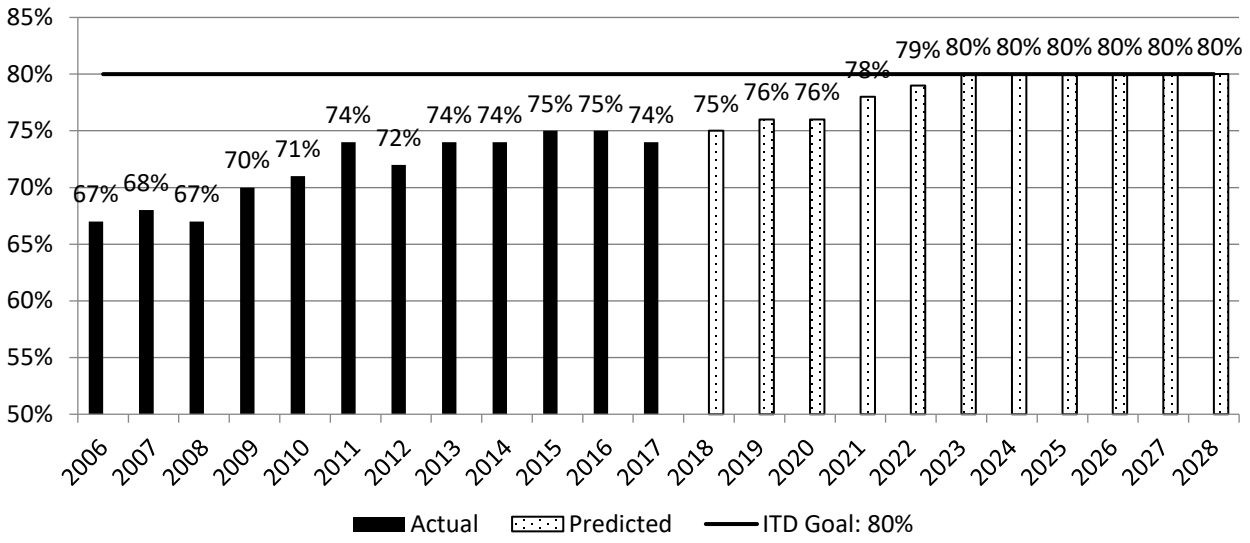

Figure 3-20: SHS Forecasted Bridge Performance

Figure 3-21, shows changes in SHS bridge conditions for the past 4 years (2015-2018). Later chapters will discuss how ITD is managing its SHS bridge assets and the strategies it is using to improve performance of the SHS bridges.

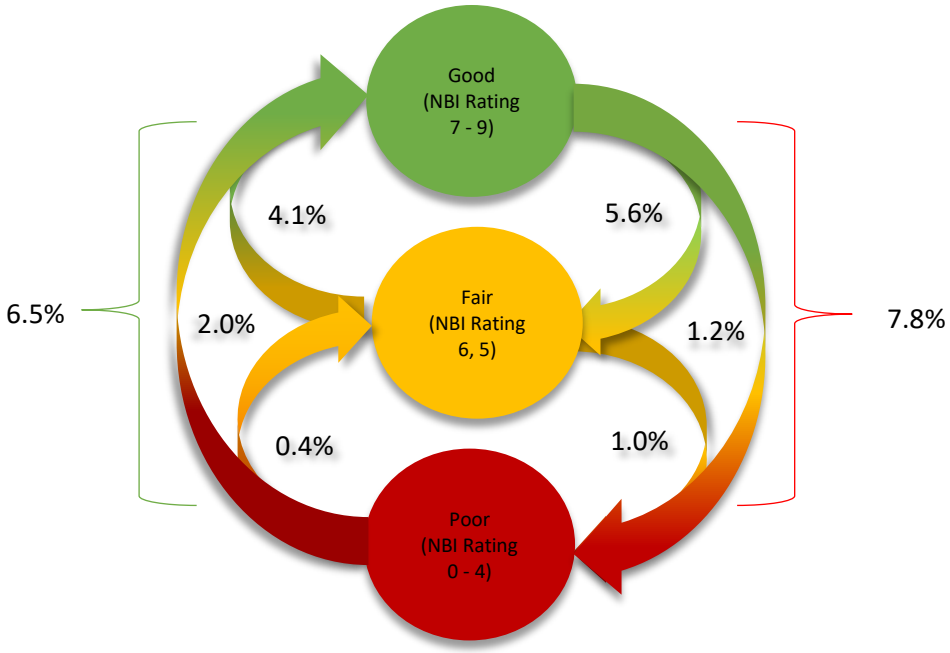

Figure 3-21: 2015 to 2018 Idaho SHS Condition Trend Bridge Performance (% Deck Area)

Idaho NHS Description of Assets

There are 870 Bridges on the National Highway System (NHS) in the State of Idaho. Consistent with the Federal definition of a bridge and as stated in Chapter 2, these are bridges, including culverts, which are longer than 20 feet in length. ITD owns and manages the vast majority of NHS bridges in the State at 92 percent, but not all of the NHS bridges are state owned. Local governments in Idaho own a small portion of the NHS at about eight percent of total deck area. The Federal Bridge Performance Measure as presented in Chapter 2 includes all of the NHS bridges in that measure. Table 3-3 shows the portions of the NHS that are owned by the State and local governments in Idaho.

Table 3-3: Bridge Ownership

Bridge Asset Class	Bridge Count	Deck Area	
		Sq. Ft.	Percent
State owned NHS Bridges	807	8,148,547	92.4%
Local owned NHS Bridges	63	667,474	7.6%
Total NHS System	870	8,816,021	100.0%
Note: Includes bridges and culverts > 20-foot in length			

Idaho NHS Conditions and Trends

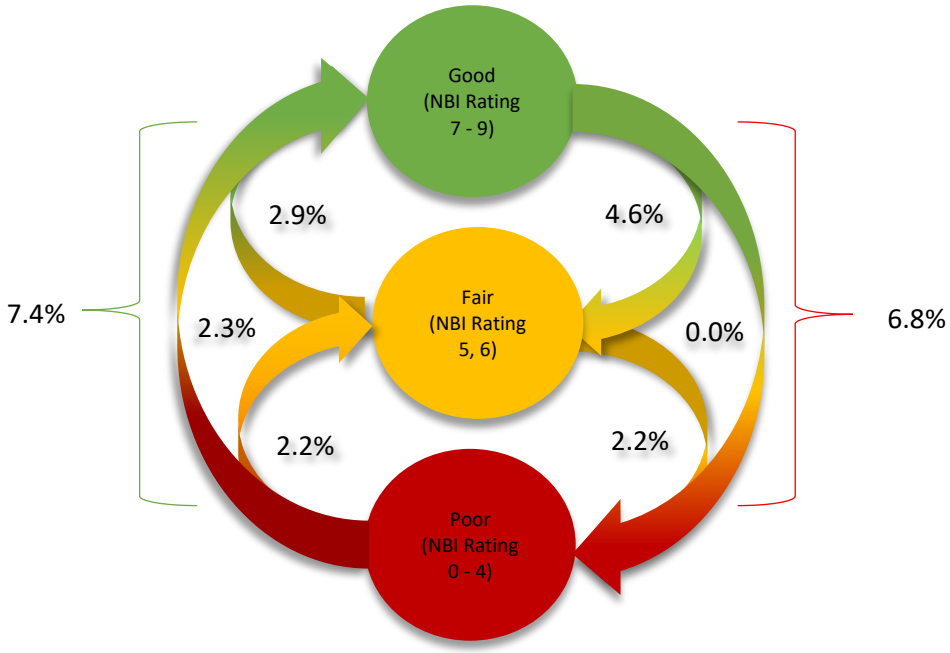
Of the 870 bridges, and over 8.8 million square feet of deck area, 19 percent, 78 percent, and three percent of Idaho's NHS bridges are in good, fair and poor condition, respectively. Table 3-4 shows the breakdown of NHS bridge assets in Good, Fair, and Poor condition as well as the portions owned by the State and the local governments. This table is based on the end of Calendar Year 2018 data.

Table 3-4: Bridge Ownership and Performance

Bridge Asset Class	Federal Condition Criteria			
	Good	*Fair*	*Poor*	*Total*
State NHS Bridges	157 bridges with 1,487,757 SF of deck area 16.9% by deck area	622 bridges with 6,378,352 SF of deck area 72.3% by deck area	28 bridges with 282,438 SF of deck area 3.2% by deck area	807 bridges with 8,148,547 SF of deck area 92.4% by deck area
Local NHS Bridges	25 bridges with 161,983 SF of deck area 1.8% by deck area	37 bridges with 502,607 SF of deck area 5.7% by deck area	1 bridges with 2,884 SF of deck area <0.0% by deck area	63 bridges with 667,474 SF of deck area 7.6% by deck area
Total NHS System	**182 bridges with 1,649,740 SF of deck area 18.7% by deck area**	**659 bridges with 6,880,959 SF of deck area 78.1% by deck area**	**29 bridges with 285,322 SF of deck area 3.2% by deck area**	**870 bridges with 8,816,021 SF deck area 100% by deck area**
Note: Includes bridges and culverts > 20-foot in length				

Using our Bridge Management system, ITD monitors not only the current performance of the NHS Bridge assets but also how that performance is changing over many years. As shown in the Figure 3-22, changes in bridge conditions for the NHS are shown for the past four years (2015-2018).

Figure 3-22: 2015 to 2018 Idaho NHS Condition Trend Bridge Performance (Percent Deck Area)



For the years 2015-2018, approximately 6.8 percent of NHS bridge deck area declined in condition. This decline in condition is largely attributable to normal wear and tear on bridges from vehicular traffic, normal deterioration from weather and exposure to the elements, as well as damage caused by unexpected events whether that be human caused or natural disasters. Through the transportation investments that ITD and the locals made in the NHS bridge assets, approximately 7.4 percent of NHS bridge deck area improved in condition. These investments came in the form of replacing worn out bridges, repairing bridges, and preserving those bridges that were in good and fair condition.

ITD is striving to hold the percentage of NHS bridge assets in good condition at 19 percent. Currently Idaho's NHS bridges are at 18.7 percent in good condition with another 78.1 percent in fair condition. Only 3.2 percent of NHS bridges are in poor condition. As stated in Chapter 2, based on current funding levels, ITD's target for NHS bridge performance is to maintain current conditions.

Later chapters will discuss how ITD is managing its NHS bridge assets and the strategies it is using to maintain performance of the NHS bridges.

Obtaining Data from Local NHS Owners

A FHWA requirement is that States develop processes for obtaining data on locally owned NHS pavements and bridges. ITD collects pavement condition annually on the entire NHS. ITD also inspects all the bridges on the NHS. Therefore, ITD will have no problem continuing to acquire condition and performance data on the entire NHS network. ITD has developed many web-based tools to facilitate communication of condition information to the various jurisdictions owning NHS assets.

Communicating the performance data is equally important to collection and analysis. In order to facilitate compiling, synthesizing and communication of performance data ITD has made significant investments to incorporate geographical information systems (GIS) within the asset management framework. Examples are presented on the following pages in Figure 3-23 and Figure 3-24.

Chapter 4 - Gap Analysis Process

FHWA regulations require the asset management plan to include a performance gap analysis which FHWA defines as the gaps between the current asset conditions and the targets for asset conditions. In addition, gaps could be issues in which asset conditions prevent the transportation system from operating effectively because of poor conditions.

By the Federal definition, ITD does not have a gap between its current pavement asset conditions and its targets for asset conditions.

ITD's bridge conditions surpass its targets of having at least 19 percent good and no more than 3 percent poor. ITD NHS bridges and Interstate pavements easily surpass the Federal minimum condition levels.

For the 2018 TAMP a gap existed in ITD's ability to use its management systems to forecast the condition of State Highway System pavements and bridges. For the 2019 TAMP ITD reports closing this gap. ITD has the ability to perform analysis for the 10 years of the asset management-planning horizon. ITD also will continue its focus on Interstate and NHS pavements to achieve the 50 percent good target level, while not exceeding its threshold for poor conditions.

Gap Requirements

The asset management rule in Sec. 515.7 (a) says, "A State DOT shall establish a process for conducting performance gap analysis to identify deficiencies hindering progress toward improving or preserving the NHS and achieving and sustaining the desired state of good repair. The asset management rule describes a performance gap as:

Performance gap means the gaps between the current asset condition and State DOT targets for asset condition, and the gaps in system performance effectiveness that are best addressed by improving the physical assets.

FHWA's guidance to its divisions that will be certifying TAMPs tells them to look for the following required elements.

The TAMP must describe a methodology, with regard to the *physical condition* of the assets, for:

- Identifying gaps affecting the State DOT targets for the condition of NHS pavements and bridges as established pursuant to 23 U.S.C. 150(d).
- Identifying deficiencies hindering progress toward achieving and sustaining the desired state of good repair (as defined by the State DOT).
- Developing alternative strategies that will close or address the identified gaps.

The TAMP must describe a methodology for analyzing gaps in the *performance* of the NHS that affect NHS bridges and pavements regardless of their physical condition that will:

- Identify deficiencies in the effectiveness of the NHS in providing safe and efficient movement of people and goods. (23 CFR 515.7(a)(2)
- Identify strategies to close or address the identified gaps. (23 CFR 515.7(a)(3))

Steps in the Gap Analysis Process

In preparation for developing and updating the Idaho Transportation Investment Program and for demonstrating asset management plan implementation, ITD conducts annual reviews of updated pavement and bridge condition data. ITD staff compares the results of the annual condition data with the forecasted

values for bridge and pavement conditions. From these results, ITD will identify gaps between actual and forecasted conditions for both the State and Federal Performance Measures and targets.

Below are the previously discussed performance measures and targets as identified in Chapter 2, along with the current conditions and gaps:

Table 4-1: Federal Performance Measures and Targets for Pavements and NHS Bridges

Asset Class	Idaho Performance Measure	2 & 4 Year Targets	Current Condition	Current Gap
Pavement *	SHS Percent Good	>80%	91%	+ 11%
Bridge	SHS Bridge Percent Good	80%	75%	- 5%
**As calculated from the ITD TAMS based on 2018 roadway data collection.*				

Table 4-2: Federal Performance Measures Gaps

Asset Class	Federal Performance Measure	2 & 4 Year Targets	Current Condition	Current Gap
Pavement*	Interstate NHS Percent Good	50%	65.6%	+ 15.6%
	Interstate NHS Percent Poor	4%	0.2%	+ 3.8%
	Non-Interstate NHS Percent Good	50%	50.8%	+ 0.8%
	Non-Interstate NHS Percent Poor	8%	0.3%	+ 7.7%
Bridge	NHS Bridge Percent Good	19.0%	18.7%	- 0.3%
	NHS Bridge Percent Poor	3.0%	3.2%	+ 0.2%
**As calculated from the ITD TAMS based on 2018 roadway data collection.*				

As shown in the table above, the gaps for NHS bridge conditions are very small in Idaho. Moreover, since more than 92 percent of NHS bridges are a part of the State Highway System (SHS), there is only one process and set of strategies discussed in this chapter for analyzing and closing the performance gaps on Idaho's bridges. That process and its strategies are being utilized to close the gap on all 1,835 SHS bridges that ITD manages.

The ITD asset management gap analysis process will consist of the following steps.

1. Quantify the amount of infrastructure improvements needed to close the gap(s), such as bridge deck area that needs to be replaced/preserved or lane miles that need rehabilitation;
2. Prepare high-level financial estimate(s) to close these gaps. Share these estimates in the Department's periodic performance management reports. Financial needs will be estimated by applying the average bridge construction unit cost data to estimate bridge investment level(s) that are needed for replacing, rehabilitating, repairing and preserving bridges.
3. Summarize and categorize functional class, NHS versus Non-NHS, Commerce routes and non-commerce routes will be analyzed for gaps and quantification of needs. Allocate the financial estimates from step two to these route systems;
4. Discuss gaps with ITD Board and strategies/investment levels to close gaps. Formulate a strategy with the Board to close gaps. This may require implementing strategies over multiple years to

align with funding, resource, or economic constraints.

5. Work with District staff to prioritize needs on the NHS, SHS, and other systems. Working from route system level needs described in step three, the Department will formulate buildable projects and program those projects which improve the overall system performance the most;
6. Vet projects through the annual Idaho Transportation Investment Program development process. Once approved, develop and build the projects;
7. Work with the Idaho State Legislature to increase transportation revenue and work with other stakeholders to identify alternative sources of funding such as public-private partnerships as needed.

Non-Condition Based System Performance Gap Analysis

ITD incorporates our mission of safety mobility and economic opportunity into our planning efforts. Some of the goals from our planning documents are provided to demonstrate this:

Freight:

- Improve the safety of operations for freight carriers in Idaho
- Enhance Idaho's freight system mobility for industries to efficiently transport goods to market
- Support the economy and the vitality of Idaho and its communities.

Public Transportation:

- Ensure the Safety and Security of Public Transportation
- Encourage Public Transportation as an Important Element of an Effective Multi-Modal Transportation System in Idaho
- Preserve the Existing Public Transportation Network
- Provide a Transportation System that Drives Economic Opportunity

Active Transportation:

- Support economic vitality that enables a high standard of living, facilitates the retention and growth of Idaho businesses, attracts new business to the state, and enables employers to attract and retain a highly skilled and creative workforce
- Develop and maintain a transportation system that is safe, effective, reliable, and accessible for residents and visitors as they use all modes to travel anywhere, from within their neighborhoods and communities to throughout the state

ITD's 2040 Long-Range Transportation Plan (pending FHWA approval) shares the same planning perspective of incorporating ITD's mission of safety, mobility by reaffirming those themes in our long-term goals:

- Commit to providing the safest transportation system possible.
- Provide a mobility-focused transportation system that drives economic opportunity.
- Become the best organization by continually developing employees and implementing innovative business practices.

ITD's 2040 Long-Range Transportation Plan incorporates the importance of asset management planning

as part of the planning process by identifying the importance of using life cycle curves that account for growth by updating conditions and traffic information on a regular basis. In addition to the highlighting of ITD's asset management planning, ITD's Long-Range Transportation Plan identifies the role of engineering and data assistance in the planning for asset life cycle versus public involvement in system management. This helps identify to the public the expectation of participation in various planning roles at ITD.

For non-asset management project selection of highway projects. ITD has a Safety and Capacity Program that strategically pools several funding sources to maximize the ability to provide projects that both enhance safety and provide additional capacity in congestion areas. Several of the funding sources are state funded and have legislatives requirements that must be met. The projects that are constructed from this program contribute to asset management by resetting life cycle curves to new or rehabilitated conditions.

ITD also has a legislatively authorized Grant Anticipation Revenue Vehicle (GARVEE) program that allows for additional improvements to state highways. There are corridors across that state that are eligible for GARVEE funds, a combination of congestion, safety and asset conditions are used by the Idaho Transportation Board for the selection of GARVEE funded projects.

Along with the process described above, ITD staff are always collaborating across the organization amongst bridge and pavement subject matter experts to include:

- Materials and Pavement Engineers;
- District construction staff and personnel;
- ITD staff who develops the Highway Safety Improvement plan;
- Those who issue truck size and weight permits;
- MPO and ITD travel demand modelers who assess travel time across the highway network, particularly in urban areas;
- Agency leadership to innovate and find ways to stretch limited transportation revenues further.

In addition, ITD is constantly analyzing its asset management data and process to:

- Determine if increased investments or tradeoffs from other programs would result in better system performance;
- Review materials, treatment types, and construction methods to find more durable longer lasting solutions;
- Continually calibrate the Department's asset deterioration curves and other elements of bridge and pavement forecasting models;
- Continually assess financial trends in the highway construction market through construction cost data to optimize advertising and letting of construction contracts;
- Assess whether increased maintenance efforts will result in cost effective gains in closing the performance gaps.

Consultation also will occur through the Three "C "planning process (continuing, cooperative, comprehensive) that occurs with the MPOs. The recent planning rule, Sec. 450.314(h) requires that States, MPOs, and operators of public transportation jointly agree upon and develop specific written provisions for cooperatively developing and sharing information related to transportation performance data, the selection

of performance targets, the reporting of performance targets, the reporting of performance to be used in tracking progress toward attainment of critical outcomes for the region of the MPO, and the collection of data for the State asset management plan for the NHS. As part of this joint, collaborative process, ITD will seek from the regional planners and operators of transit agencies any identified gaps that impede achievement of the safe, efficient movement of goods or people on the NHS.

As part of finding solutions to close performance gaps, ITD will use its planning and asset management process to develop alternative investment strategies to present to the Idaho Transportation Board. In order to present several alternatives to the Board, ITD staff will:

- Run several iterations of bridge and pavement investment strategy scenarios using the bridge and pavement models. These iterations will be run to ensure optimal balances between asset classes are being achieved;
- Analyze several investment scenarios. These scenarios could include varying levels of increasing investments in assets and tradeoffs between asset classes.
    - Additional scenarios could also be run to address specific concerns. For example, ITD would analyze the effects of increasing bridge investments if posted structures were found to be restricting freight movement on NHS connectors or other key routes.
- Review maintenance strategies to determine if any of the gaps could be alleviated through a shift in maintenance forces and resources;
- Make adjustments in targets;
- Promote adoption of new or different materials or treatments if, for example, a new material emerges that is superior to conventional methods and practices;

As alternative strategies are developed, they will be presented to the ITD board along with their implications related to funding, tradeoffs with other asset classes, and/or their impact on system performance. At the direction of the Idaho Transportation Board, the approved strategies will be implemented to address the performance of the SHS and NHS and to close performance gaps.

Process Improvements Completed

As part of the 2018 TAMP, ITD identified that there was a gap in the pavement performance module. Extensive work occurred to close this gap resulting. This effort was part of the continuous improvement process that ITD applies to all of its asset management efforts.

These specific system enhancements have been completed and implemented in 2019:

1. Revision to performance models and analysis of actual performance to comply with FHWA requirement to report and forecast performance on 1/10-mile interval out to the required 10-year horizon.
2. ITD developed and incorporated a process to model and forecast the FHWA specified performance measures.
3. ITD TAMS Database was modified better track and report out ITD targets for each asset class or asset sub-group into the LCCP analysis.

Additional Process Improvements

Even with current asset management systems in place and performance management well integrated into the culture of ITD, the Department continues to take steps to enhance several asset management processes. These enhancements will improve the accuracy of future asset management plans and further optimize the Department's management of its road and bridge assets. Planned enhancements include:

ITD will continue developing the BrM Bridge Management System. ITD has been using the AASHTO Bridge Management system known as "BrM" for many years to house current and historical condition data for bridge assets. While condition data collection and storage is well engrained at ITD, the bridge deterioration forecasting, modeling of future conditions and investment scenario optimization modules are still relatively new. Further, the software vendor is still developing these modules to improve forecasting reliability and accuracy. ITD is currently implementing these additional modules of BrM to complement the multi-objective optimization processes that ITD has been using for many years. The multi-objective process is discussed in Chapter 5. ITD will continue to implement the deterioration forecasting, modeling, and scenario optimization modules in BrM to enhance its bridge asset management processes. This work is partially dependent upon improvements being made to BrM by the software vendor.

ITD commits to the following work plan for bridge management process improvements:

- Continue to refine BrM decision trees to reflect ITD policy by 2020;
- Continue to calibrate BrM deterioration models to match Idaho's historical bridge performance by 2021;
- Continue to incorporate cost/benefit analysis and life cycle cost analysis into ITD's planning and programming (STIP) by 2021.

Assess the long-term consequences of the Non-Commerce Route treatments. ITD has divided all routes into Commerce and Non-Commerce routes. Non-Commerce routes handle less than 300 trucks per day. Because of higher priorities in other programs, ITD has limited for several years the treatments on Non-Commerce routes to preservation-type treatments and is not funding structural repairs to Non-Commerce pavements. Although Non-Commerce pavement conditions improved from 2015 to 2016, many district staff expressed concern that the strategy is not sustainable. They fear that only applying chip seals or thin surface treatments will lead to pavement structure deterioration that will be costly in the long term to correct. ITD will assess the long-term effects and determine the degree to which the Non-Commerce routes can be sustained with the current policy.

Assess the Long-Term Needs of ITD's Largest Bridge Structures. ITD's ten (10) largest bridges by deck area have an average age of 31 **-** years old and comprise 1,525,306, square feet of deck area. Just these 10 bridges out of the 1,835 represent 12 percent of all bridge deck area on the SHS. These bridges are on key routes carrying some of the highest traffic volumes in the State and often are key crossings with long and costly detours around them if one or more were closed or restricted to traffic. Several of them have current conditions in the fair range and are expected to decline due to normal wear and tear as these bridges continue to age. Within the next 20 years, several of them will need major rehabilitation, which will create inordinately high costs for ITD.

To plan for these costly investments, ITD has begun developing individual Bridge Asset Management Plans

for eight high cost replacement bridges in ITD's inventory. Most of these bridges are on the NHS. Individual asset management plans are being developed for each bridge and will contain a detailed management strategy specific to that bridge. This detailed information helps ITD to create an optimal plan and schedule of bridge preservation and rehabilitation activities to extend these bridges' service lives to as far as 100 years. In addition, the plans are also developing strategies for the ultimate and very expensive replacement action that will eventually be needed when each of these bridges reach the end of their service lives.

These individual asset management plans help ITD manage these assets, which are larger, more complex, and costly than the typical assets in ITD's bridge inventory. The information helps ITD to analyze future funding scenarios and investment tradeoffs to ultimately pay for replacing these expensive assets. ITD plans to develop additional individual asset management plans for other large and complex bridges in ITD's inventory.

ITD will define processes and modify required systems to forecast and report financial investments on the NHS for all five work types as well as define basis of unit costs for work types.

Although Chapter 7 does show the funding forecast across four of the five work types as defined in 23 CFR 515.5, ITD will continue to develop, document, and refine the processes employed to determine work type unit costs for NHS pavements and bridges. Specific improvements will include the following:

- ITD will define and document five work types (as defined in 23 CFR 515) as well as the activities that are applicable to each work type by 2021;
- Defined and document a process ITD uses to estimate maintenance and work type expenditure for NHS bridges and pavements and develop a process for determination of average annual work type costs for these facilities by 2021;
- Work with executive management to refine programing categories on the STIP to refine funding categories as to eliminate confusion with work types by 2021;
- Develop capability to report actual and programed NHS expenditures by work types by 2021.

ITD will define a process and dedicate personnel responsible for coordinating with local agencies on Local NHS.

ITD commits to defining a process and personnel to ensure coordination with local agencies owning part of the NHS. In 2019 ITD has designated within the Asset Management section dedicated personnel responsible for ensuring asset data is collected, processed, and reported back to local NHS owners. Specific actions will include the following:

- Development of a Standard Operating Procedure for how information is collected, processed, forecasted and communicated between ITD and local agencies in support of TPM requirements by 2021;
- Conduct meetings with each agency during each fiscal year by 2021;
- ITD will communicate the local agency current NHS performance, forecast future performance, model proposed treatments, and make recommendations for future treatments;
- ITD will incorporate any local NHS planned projects into performance models and forecasts.

Chapter 5 - Life Cycle Planning Process

Life Cycle Planning Requirements

The federal asset management regulation says that each state must have a process for managing the life cycle of the assets included in the asset management plan.

FHWA provides several definitions relevant to how it wants states to approach Life cycle Cost Planning (LCP) and Life cycle Cost Analysis (LCA). Life cycle Cost Analysis means the cost of managing an asset class or asset sub-group for its whole life, from initial construction to its replacement. Life cycle planning means a process to estimate the cost of managing an asset class, or asset sub-group over its whole life with consideration for minimizing cost while preserving or improving the condition.

For the pavements and bridges included in the asset management plan, FHWA wants the state to document how it is managing them to reduce the total life cycle cost through the timely and appropriate application of preservation, maintenance, rehabilitation, and reconstruction at the appropriate times in the assets' life cycle.

Life Cycle Planning Requirements

The asset management rule says in Sec. 515.7 (b)

"A State DOT shall establish a process for conducting life-cycle planning for an asset class or asset subgroup at the network level (network to be defined by the State DOT). As a State DOT develops its life-cycle planning process, the State DOT should include future changes in demand; information on current and future environmental conditions including extreme weather events, climate change, and seismic activity; and other factors that could impact whole of life costs of assets. The State DOT may propose excluding one or more asset sub-groups from its lifecycle planning if the State DOT can demonstrate to FHWA the exclusion of the asset sub-group would have no material adverse effect on the development of sound investment strategies due to the limited number of assets in the asset sub-group, the low level of cost associated with managing the assets in that asset sub-group, or other justifiable reasons. A life-cycle planning process shall, at a minimum, include the following:

(1) The State DOT targets for asset condition for each asset class or asset sub-group;

(2) Identification of deterioration models for each asset class or asset subgroup, provided that identification of deterioration models for assets other than NHS pavements and bridges is optional;

(3) Potential work types across the whole life of each asset class or asset sub-group with their relative unit cost; and

(4) A strategy for managing each asset class or asset sub-group by minimizing its life-cycle costs, while achieving the State DOT targets for asset condition for NHS pavements and bridges under 23 U.S.C. 150(d).

Data and Management System Requirements

Additionally, FHWA regulations require that states use their bridge and pavement management systems to analyze the condition of NHS pavements and bridges and to develop and implement

the asset management plan. The regulations set six major requirements for what the management systems provide. Furthermore, FHWA regulations require that states document that they use the "best available data" when developing their asset management plans.

This section explains ITD's:

- Definitions for Exclusions to Life Cycle Planning Process
- Approach to Life Cycle Planning Process
- Use of it management systems to develop and implement its life cycle analysis and asset management plan, and
- Use of the best available data to develop its asset management plan.

ITD has established processes for data collection, monitoring, and reporting for system performance across each asset class. With respect to pavement Life Cycle Planning, the ITD PMS utilizes a slightly different classification schema, which is based on the given taxonomy shown in Figure 3-3 on page 3-3. Specifically, ITD defines four network facility types, interstate, statewide, regional, and district. As discussed further in this chapter, IDT utilizes these classifications to priorities treatments to the higher functional classified routes. That is not to say, lower class routes are excluded from consideration, merely, performance criteria is more stringent for the higher type facilities.

+Overview of Life Cycle Planning

The concept of Life Cycle Planning (LCP) requires a focus on all costs associated over the expected life cycle of an asset and provides a systematic approach to ensure the most appropriate choices are made to maximize the value of an asset.

Organizationally supported, Life Cycle Cost Planning has been in practice for many years at ITD. For instance, construction decisions that only consider immediate costs of a project, and fail to consider long-term preservation and operations cost, do not provide the best value for an asset. Following that rationale, consider the following example: most of the small fixed bridges are built using concrete and not timber, even though the initial cost of a timber bridge would be a fraction of a concrete bridge cost. Consider for instance, that timber bridges have limited load capabilities, can wear out quickly, and require almost continuous maintenance. Compared to the life span of a concrete bridge, the timber bridge would be rebuilt several times. LCP appropriately factors in all the down time, user detour and delay costs, material cost, labor cost, replacement cost, life expectancy, etc. to help determine that the concrete bridge is a superior long-term decision. The LCP concept supports sound agency decisions.

Typically, an asset is well maintained when it is maintained at a level that minimizes long term costs and is still kept in good condition so that it performs at the level it is needed. Over the life of an asset, well-timed preservation activities can cut life cycle costs by as much as half when compared to a policy where no preservation is performed. In relative terms, repainting a house at the most appropriate time, but not too soon, allows maximization of the value of your previous paint job, while not resulting in exposure of wood to long-term damage. Preservation treatments in this context will include repaint, repair and repaint, replace and repaint with each having a higher long-term cost. If nothing is done and the roof caves in, reconstruction is required. While these simple examples illustrate the concept, in reality, the decisions are not always that simple, and they need to be applied to thousands of assets each on its own life cycle

with a set of potential actions an owner can take to minimize cost.

LCP Deterioration Curves

To ensure making appropriate choices, LCP endeavors to find the optimal level of preservation to minimize long-term costs. Ideally, preservation expenditures should neither be applied too frequently nor delayed too long. Figure 5-1 shows how relatively inexpensive treatments, early in the life of an asset, maintain the asset in nearly excellent condition while effectively extending the life of the initial investment significantly. Conversely, the "do nothing" approach does not allow the asset to reach its expected service life effectively and has the consequence of very rapid deterioration later in the asset's life. This graph provides a simplified depiction of the life-extending benefit of a preventive maintenance treatment. The vertical axis indicates the condition of the pavement, from poor to fair to good. The horizontal axis indicates time in years. The graph shows two downward curves, a typical pavement deterioration curve that goes downward from good to poor as the years pass and, above it, a shorter, flatter life extension curve. Both curves begin within the "Good" condition segment of the axis; however, the life extension curve begins in a later time period. Each curve is made of data points at intervals measured using a pavement management system. The deterioration curve is interrupted at a by a life-extension arrow showing that a preventive maintenance treatment has been applied. A second line extends upward from the point of treatment to the life extension curve's starting point (within the "Good" area), showing that the preventive maintenance has restored the pavement's condition to "Good." The life extension curve slopes downward from this starting point, as the pavement returns to the condition it was in before the treatment. The length of the life extension curve represents the extended service life gained through the preventive maintenance treatment. The data points on the two curves indicate that periodic measurements of pavement condition before and after the preventive maintenance makes it possible to determine the extended service life of a treatment.

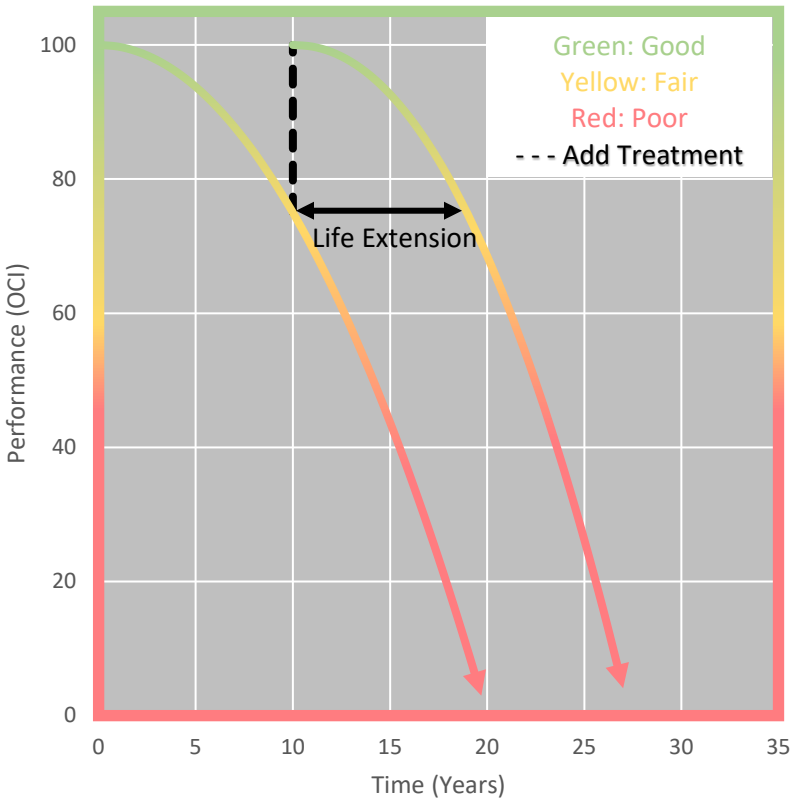

Figure 5-1: Schematic LCP Deterioration Curve

When faced with budget limitations, LCP requires the difficult decision that some of the assets that are nearing the rapid deterioration phase, and thus requiring major rehabilitation and large expenditures, be sacrificed and allowed to

reach their end of life (and very poor condition) in order to more appropriately spend the available dollars to get the maximum cost benefit for the remaining assets in the entire asset pool. The tools in ITD's Pavement Management System (PMS) and Bridge Management System (BMS) provide the capability of evaluating this trade-off.

Treatment Definitions

All physical assets deteriorate with age and use. As assets deteriorate, applying appropriate treatments can slow or repair that deterioration. In general, treatments are categorized by their impact and cost:

- **Corrective maintenance treatments** generally involve repairs to specific elements or aspects of an asset. These treatments are typically used for assets that are in fair to good condition, but in need of specific repairs. Examples of corrective repairs include replacing a leaking expansion joint on a bridge or bump grinding on pavement. These types of treatments are not part of ITDs LCP approach.
- **Preservation and Resurfacing treatments** typically arrest minor deterioration without significantly improving condition or provide a modest improvement in condition. While these types of treatments do not provide a significant improvement in condition, they are very effective at extending the time an asset remains in good or fair condition. Examples of preservation maintenance treatments include bridge deck sealing, pavement crack sealing, thin pavement overlays, and chip sealing.
- **Restoration treatments** are similar to preservation treatments except that they are more in depth. Restoration treatments seek to arrest moderate deterioration and correct defects such as rutting or concrete overlay of a bridge deck. These treatments are usually applied to assets in fair condition with the intention of bringing them back into the good condition realm.
- **Rehabilitation** is required for assets, which still have a potential for significant remaining service but have a substantial number of components in need of repair, or major components in need of substantial repair. These treatments are usually applied to assets in poor condition with the intention of bringing them back to good condition. Examples of rehabilitation treatments include bridge deck replacement and thicker pavement milling and inlay.
- **Replacement/reconstruction** is required when an asset has reached the end of its service life and can no longer be extended though repair or rehabilitation. This is a complete rebuilding project and resets the asset's service life.

Pavements

ITD's pavement management system conforms to the requirements set out in the federal asset management rule. The description in this section explains that ITD uses:

- its pavement management system for life cycle planning;
- the best data available for LCA;
- PMS to develop and implement its asset management plan.

Background

The Idaho Transportation Department has over a 40-year history of collecting and reporting pavement performance data as well as implementing pavement management systems (PMS) with the ever-present desire of obtaining the greatest longevity for the minimal cost and ensuring good stewardship of the roadway system with which we are entrusted. As shown in Figure 5-2, ITD began utilizing computer programs to track pavement performance in the late 1970's. Although rudimentary by today's technology standards, ITD demonstrated a desire to utilize emerging technology more holistically to manage pavements. By the mid-80's this PMS was able to perform very simple economic trade off analysis between competing pavement needs. This experience in economic forecasting and assessment has continued to this day for determining economic benefits between competing projects. In 2007, ITD decided to replace the existing PMS with the Highway Economic System (HERS-ST) PMS. Utilization of HERS-ST proved difficult and analysis parameters did not reflect the Idaho climate or organizational decision process. In 2009, ITD decided to phase out HERS-ST. This long history and commitment to effective pavement management is directly attributable to Idaho roads being in an excellent state of good repair.

In 2009, ITD purchased an asset management software package from Agile Assets called TAMS. This new software has a Pavement Management System (PMS) and a Maintenance Management System (MMS) to work in tandem as part of the Department's long-term vision for asset management. Fully integrated by 2011, AgileAssets Pavement Analyst System became the official ITD PMS. This software contains a robust database that houses several kinds of data, such as bridge condition surveys, maintenance activities, pavement condition ratings, traffic data, friction data and several others.

At the time of the software procurement, ITD identified the value of engineering input during setup of this PMS. ITD hired Kercher Engineering Inc. (KEI) to develop the framework and configure the software for ITD with input provided by an expert panel of ITD staff members. The expert panel consisted of members of ITD Headquarters, pavement management, materials, and IT departments, as well as District Office staff from around the state. The outcome of this initial implementation phase was a fully functional pavement management system that included the most up-to-date and best knowledge available. In 2011, ITD brought back KEI for a Phase II implementation of performance model refinement. This process included the review of past historical condition data to determine if the original expert panel developed models should be revised. The outcome of the Phase II work was adjustments to the models based on the data analysis.

In 2014, Phase III of the engineering support for PMS was given notice to proceed. This phase of the work included the refinement of the configuration and included development of condition-data-collection processes to better define condition indices. This phase also included many adjustments to the overall decision-making and performance-modeling framework. A field review of pavement conditions was carried out to provide additional insight into the deterioration trends of the state's pavements. Finally, performance measures and overall business rule changes were made that required reconfiguration in PMS.

ITD continues become more efficient in data management. Part of this evolution is changing the way in which we reference and refer to the location of roadway locations. The current PMS referencing basis uses segment codes and mileposts. This system has evolved and been utilized for many decades. How-

ever its' utility is rapidly nearing an end as Geographic Information Systems (GIS) based on mapping coordinates (Latitude / Longitude) become more widely utilized. Founded on GIS principles and based on geospatial coordinates newer PMS systems, even that provided by the current vendor, require the use of a Linear Reference System (LRS). ESRI Roads and Highways is the GIS platform ITD has chosen to implement for LRS. ITD has undertaken a project to identify, assess and implement a newer version of Asset Management Software compatible with ESRI Roads and Highways.

The PMS has allowed ITD to refine the way it invests in and maintains pavement by:

- Implementing new pavement performance curves calibrated by ITD engineers;
- Implementing decision trees that mimic ITD District engineering choices;
- Creating performance models that accurately track and display pavement projects;
- Employing an analysis engine that uses integer optimization to maximize benefit.

These components directly address and satisfy FHWA's requirements for the functionality of pavement management systems.

With all users of the PMS having instant access to all available data, the system gives the District pavement designers and engineers an extensive toolbox at their disposal. It also gives Headquarters Asset Management engineers an equitable method to distribute funding throughout the state based on predicted and modeled need. The system suggests optimized pavement project choices based on budget constraints, which the engineers balance against needs and their expert knowledge of the system. Figure 5-3, is a high level overview of how roadway performance data is aquired, utilized, and reviewed in concert with the development the State Transportation Investment Program (STIP). The PMS is aligned with, supports and facilitates each step of the pavement lifecycle data flow. Central to the is process is a review of the existing system performance and forecasting future performance based on the project decision made today.

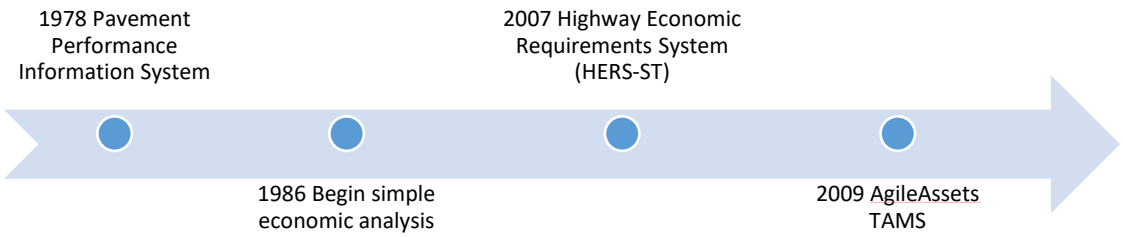

Figure 5-2: ITD Pavement Management Historical Timeline

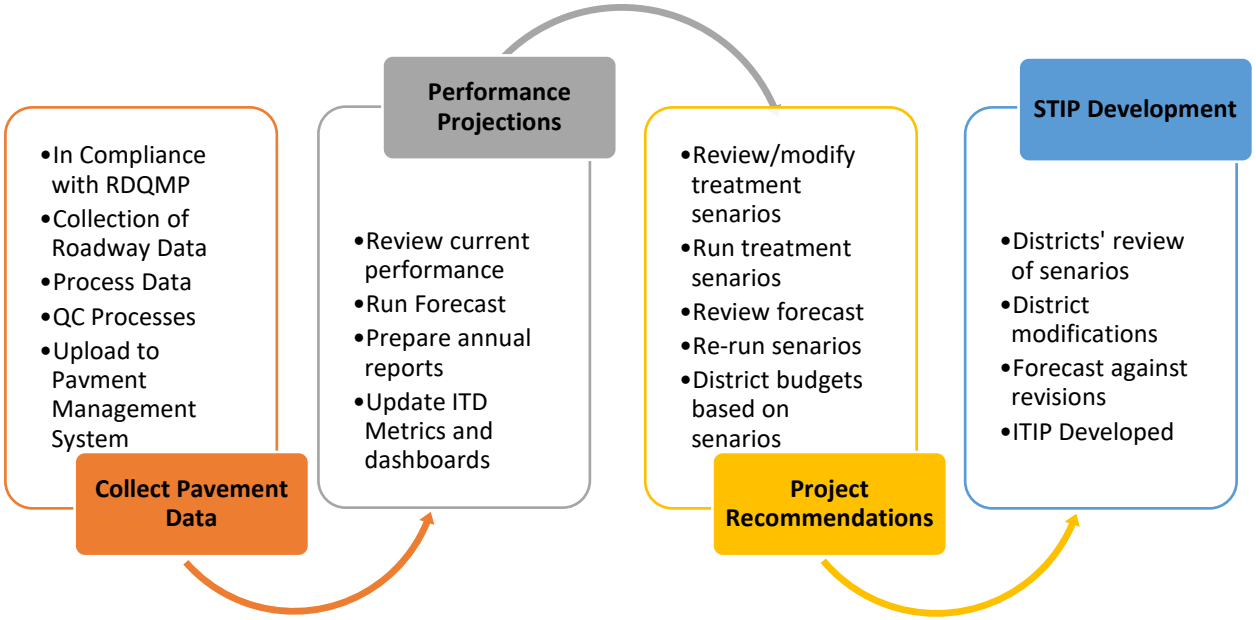

Figure 5-3: Pavement Lifecycle Process

Data Collection

Idaho collects pavement data annually using a Pathways Profiler Van, Dynatest Pavement Friction Tester (PFT), and a Dynatest Falling Weight Deflectometer. The asset management engineer performs an annual inspection with a district representative. The Profiler van drives the same highways, collecting thousands of miles of video images, rutting data, and roughness data.

The Path Runner Profiler Van

Since 1995, Idaho has used PathRunner Profiler van technology to gather the majority of the roadway data. The initial road profile van was replaced in 2007. In 2017, ITD purchased a replacement road profiler van, greatly enhancing the data quality and quantity that we are able to obtain and process. The profiler van drives every mile of the SHS and digitally records its condition. From that data, the Pavement Analysis section extracts pavement performance data, which includes cracking, roughness, faulting and rutting depth.

Figure 5-4: ITD's Profiler Van

ITD retains 5-years of video for reference. Additionally the video images from the forward facing cameras as well as the pavement surface are available to anyone using a windows based computer online at:

http://pathweb.pathwayservices.com/idaho/

Pavement Friction Testing (PFT)

Figure 5-5: ITD's Pavement Friction Tester (PFT)

The Department collects friction data (a number typically between 20 - 100, with the higher numbers representing a higher friction value) by towing a trailer that measures the force on a wheel that is locked but not rotating (i.e., skidding). This test is conducted in accordance with ASTM E 274. The friction represents the friction experienced by tires traveling on the pavement surface while wet. The pavement engineers can use this number to calculate whether a pavement needs a sealcoat or other remedy to improve surface friction. Data collection occurs every other year on state routes and annually on the interstate system. The Friction Testing Truck is calibrated to 40-mph. During collection, it is not always possible to maintain this speed due to safety concerns (i.e. speed differential on interstate) or roadway geometrics in mountainous terrain. As such, values measured outside of 40-mph may report friction values higher or lower than actually are present. To mitigate this, ITD in partnership with the University of Idaho, began a research project in 2017 to develop a correlation between the calibrated collection speed and actual speed of collection. As of this report, data has been collected through out every district on a wide variety of pavement types. Based on this data, a correlation protocol is being developed. In addition to further controlled testing and validation of the protocol, during the 2018-19 collection cycle recorded data will be adjusted with this protocol. The implication of this is that ITD will be able to more fully use all data collected.

Falling Weight Deflectometer (FWD)

The FWD is a non-destructive testing device used to complete structural testing for pavement rehabilitation projects, research, and pavement structure failure detection. The FWD is a device capable of applying dynamic loads to the pavement surface, similar in magnitude and duration to that of a single, heavy, moving wheel load. The response of the pavement system is measured in terms of vertical deformation, or deflection, over a given area using seismometers. ITD collects this data on sections of state highways that are eligible for paving projects, and uses the results to design the new pavement.

Figure 5-6: ITD's Falling Weight Deflectometer (FWD)

The FWD consists of a trailer mounted non-destructive pavement-testing unit towed behind an F-250 pickup. Data collected from this equipment is used to evaluate the strength of both flexible (AC) and rigid

(PCC) pavements. The evaluation includes base and subbase materials, checking load transfers across PCC joints, and detecting voids under the pavement. The Department has initiated a pilot program to explore the use of Ground Penetrating Radar (GPR) to visualize the pavement sub-surface structure. The intent is to provide the pavement engineer better data from a continuous scan of a section rather than just the 1/10th or ½-mile data from the FWD and borings. This will enable them to better estimate and plan for variations in sub-surface conditions when programming roadway improvements. ITD also began collecting network level GPR scans of all commerce routes in the state. This effort was completed summer of 2017.

Performance Projections

ITD has demonstrated alacrity in collecting and processing data as well as converting data into information useable to assess current and future system performance. The following sections detail the performance criteria utilized within the ITD PMS based on the data ITD annually collects.

FHWA Performance Criteria

As detailed in Ch. 2 and Ch. 3, ITD collects data supporting FHWA performance reporting criteria.

Overall Condition Index (OCI)

The standard that ITD uses for assessing pavement conditions is the Overall Condition Index (OCI). It is a general health indicator of the network measured on a 0 to 100 scale, where 100 is perfect condition. The Overall Condition Index is the performance metric that replaced the Cracking Index previously used by ITD. Compared to the process for obtaining Cracking Index, the Overall Condition Index is a more defensible, quantifiable measurement that can be used to give an accurate account of the current and future condition of the network based on the various funding scenarios that will be analyzed in PMS. The following breakdowns are used at a minimum:

- Network OCI (Weighted Average)
- OCI by District
- OCI by roadway functional classification

Condition Categories

In addition to reporting the trend of Condition Indices for various funding scenarios, it can be very useful in reporting the condition index in terms of categorical value ranges. This provides non-technical consumers of the data a quick snapshot of the breakdown of network condition without needing to understand the details of the scores directly. Typically, the data is provided in terms of percent lane miles of the network in each condition category as shown below. There are many useful metrics that can be reported similarly, and the data could be broken down by other attributes such as by district and/or classification.

Backlog of Funding Needs

This is a metric ITD uses to describe the unmet monetary needs to bring the network to good condition. In each year of the analysis, there will be roads that will not be funded due to the limited budgets available. The cost to fix these roads in each year can be summed up to provide a metric for the money needed that was not available. This can be a very useful performance measure to track how well the agency is doing to minimize the increase in backlog or the money needed to lower or eliminate it. Legislators tend

to find this type of metric easy to understand given that it is quantifying network condition in terms of dollars. By monetizing pavement deterioration, it provides a metric that allows ITD to illustrate the change in condition in terms of money. For example, if the funding level is increased by $50 million over the next ten years, it will eliminate $150 million in pavement deterioration (backlog); we have found elected officials are more likely to react to change in "dollars" than change in a condition index. In other words, if they do not spend the $50 million, they will have $150 million of pavement deterioration that will have to be fixed at some point.

Performance Measures for Life Cycle Planning

In addition to the OCI and backlog of funding needs, ITD also will produce analysis in its life cycle process and for its asset management implementation of the new federal pavement performance measures, those being:

- IRI
- Rutting
- Cracking
- Faulting

The scenarios considered by the PMS will forecast the network conditions by these new Federal performance measures, which also are incorporated into this asset management plan, see Chapter 4, page 4-5.

Project Recommendations

Performance Model Development

The Performance Models in the PMS are used to predict pavement performance into the future in an Optimization Analysis. As a component to the development of Performance Models, KEI and ITD completed field condition data reviews. In addition, the data gathered in the field was then brought into the office for processing by plotting the pavement ages versus the Distress Indices in an attempt to develop performance trends.

Pavement Performance Model Tree Structure

The Performance Model Tree Structure uses a tree node structure to group similarly performing roads into model groups based on defined sets of attributes. The Performance Model Tree Structure takes each Performance Model Type Category, defined by the Pavement Type and Repair Category, and assigns the correct Performance Model to each node.

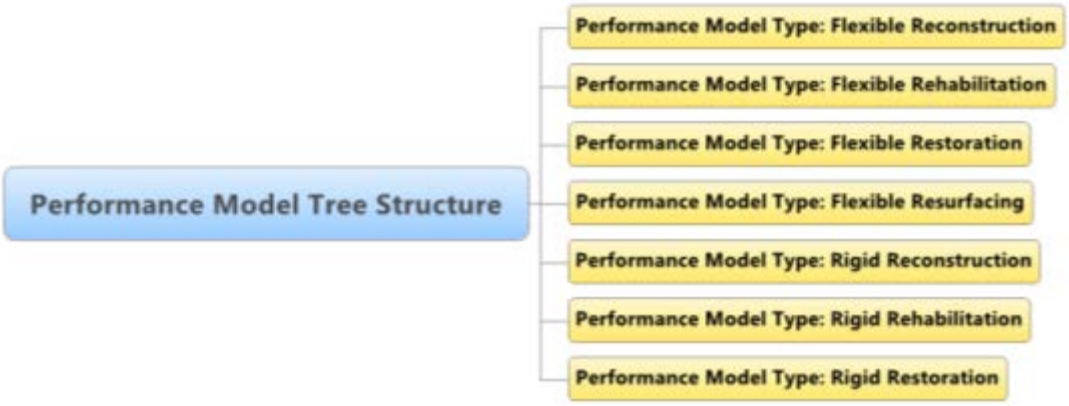

Figure 5-7: Performance Model Tree

Treatment Repair Category

Pavement performance is closely linked with the treatments that are placed on the pavement through its life cycle. The models developed are specific to Idaho based on the process described above. The Performance Categories that are used for performance modeling are listed below.

- Reconstruction
- Rehabilitation
- Restoration
- Resurfacing
- Preservation

In addition, Preservation treatments deteriorate under specific rules. The life expectancy of these treatments was provided by ITD staff as typical representations of field performance of these treatments. The Figure 5-8 identifies the key model points for the various Repair Categories. The final Piecewise Linear Models are shared across the Structural Distress, Non-Structural Distress, and OCI Indices for the Repair Categories.

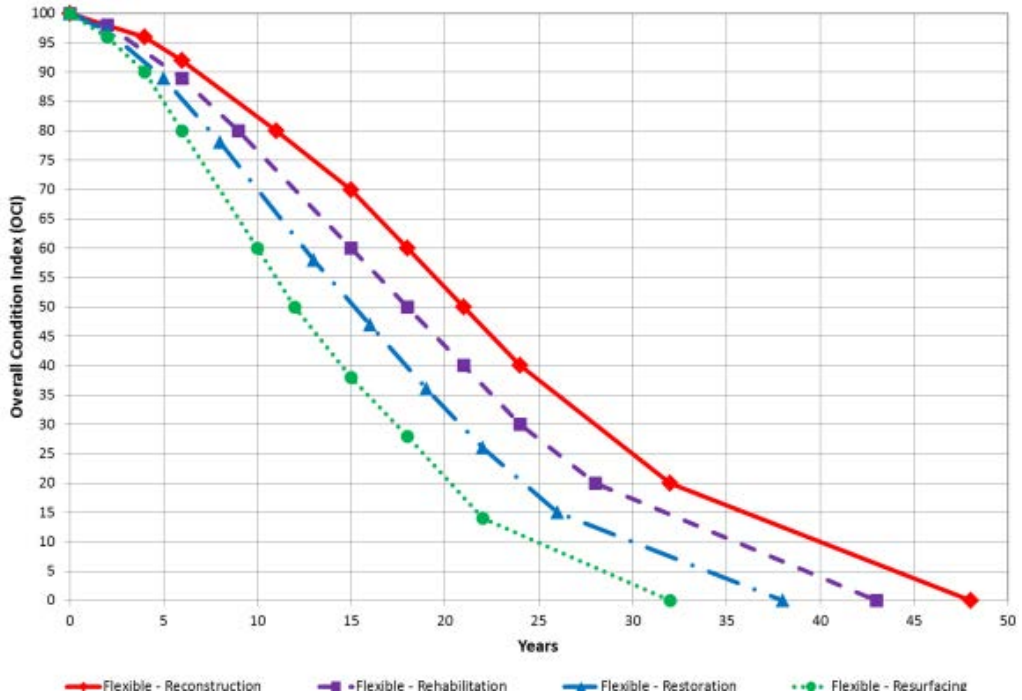

Figure 5-8: Flexible Pavement Performance Models – All Indices

Table 5-1: Expected Performance of Asphalt Pavement Treatments

Year	Resurfacing	Year	Restoration	Year	Rehab.	Year	Reconst.
0	100	0	100	0	100	0	100
2	96	2	97	2	98	4	96
4	90	5	89	6	89	6	92
6	80	8	78	9	80	11	80
10	60	13	58	15	60	15	70
12	50	16	47	18	50	18	60
15	38	19	36	21	40	21	50
18	28	22	26	24	30	24	40
22	14	26	15	28	20	32	20
32	0	38	0	43	0	48	0

Field review did not yield reasonable results for Rigid Pavement Performance Models due to most of the test sections being newly constructed; the models will be the same for OCI, Joint, and Slab Indices until ITD can carry out a more thorough data analysis plan. The Performance Models by Repair Category will remain as they are currently defined in PMS for the engineering configuration of rigid pavements.

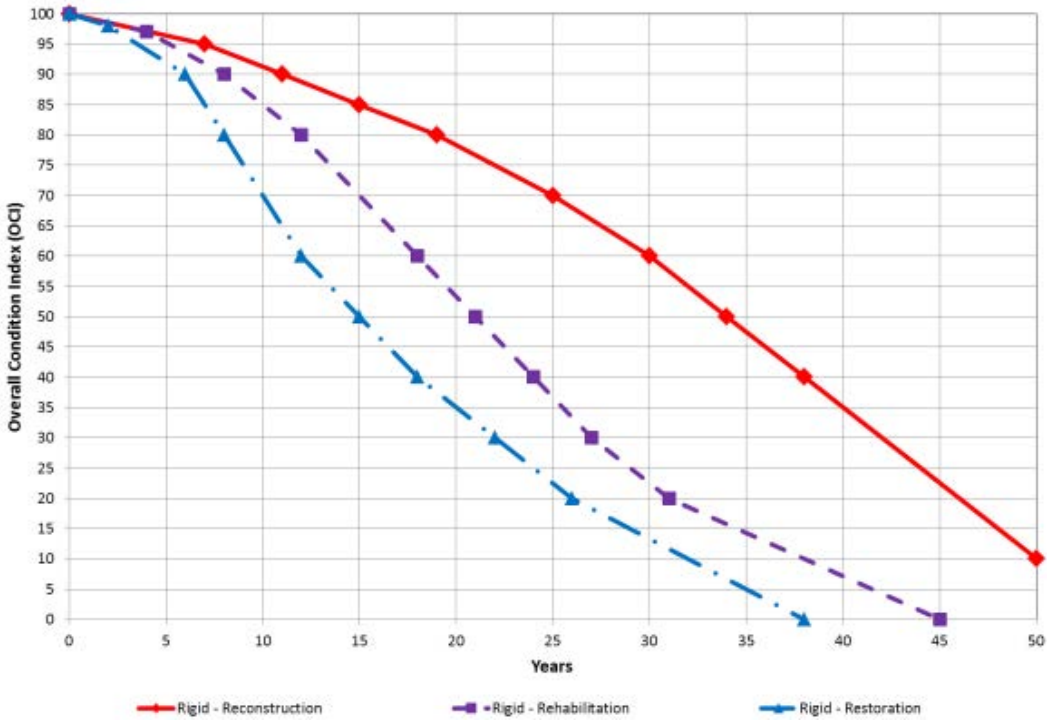

Figure 5-9: Rigid Pavement Performance Model – All Indices

Table 5-2: Concrete Performance Models by Repair Categories

Year	Restoration	Year	Rehabilitation	Year	Reconstruction
0	100	0	100	0	100
2	98	4	97	7	95
6	90	8	90	11	90
8	80	12	80	15	85
12	60	18	60	19	80
15	50	21	50	25	70
18	40	24	40	30	60
22	30	27	30	34	50
26	20	31	20	38	40
38	0	45	0	50	10

Pavement Treatment Unit Costs

ITD understands that the pavement treatment unit cost determination is critical to the accuracy with which the PMS can forecasts cost. Table 5-3 reports the current unit cost incorporated into the PMS. Costs are defined based on the treatment types forecasted (preservation, reconstruction, rehabilitation, resurfacing) and type of pavement (rigid or flexible).

Table 5-3: ITD Treatment Unit Costs

Treatment	Average SY Cost	Estimated Cost Per Lane Mile
Preservation - Flexible	$4.00	$28,160.00
Preservation - Rigid	$10.00	$70,400.00
Reconstruction - Flexible	$75.00	$528,000.00
Reconstruction - Rigid	$110.00	$774,400.00
Rehabilitation - Flexible	$33.00	$232,320.00
Rehabilitation - Rigid	$46.00	$323,840.00
Restoration - Flexible	$20.00	$140,800.00
Restoration - Rigid	$18.00	$126,720.00
Resurfacing - Flexible	$12.00	$84,480.00

Unit costs are derived using a combination of analogous and parametric estimating techniques. To develop analogous estimates, current project construction costs and quantities are reviewed by the asset management section. The estimates derived from project reviews are then validated using a parametric procedure, which is defined in the ITD design manual. Recently, ITD has created a Construction Cost Management section. Future unit costs will be derived utilizing the expertise within this section.

Pavement Management System (PMS) Configuration

One of the most important aspects of ITD's PMS is the comprehensive analysis of the various pavement condition indexes, and their use as triggers, identifying timely preservation or rehabilitation treatments that enhance and maximize potential life cycle cost benefits. The PMS software is used to analyze this data to determine a recommended treatment for each segment of roadway based on unlimited funds, essentially defining the base need. Recommended treatments have a fixed life, because the pavement continues to deteriorate, so the next step is to generate recommended treatments for a given time period based on a defined budget. When there is a need to select a treatment contrary to the PMS recommendation, the District must justify and document the request. For example, if a minor preservation treatment is recommended, and oil/gas water fracking trucks have traveled over that pavement, the recommended preservation treatment might no longer be a valid selection and must be adjusted.

In order to ensure that the treatments recommended are in line with the Department's objectives and goals, the PMS was calibrated and configured. In 2015, ITD developed a PMS Configuration Document that details the means and methods that were used to configure the PMS. Table 5-4 provides an overview of the pavement management system variables that were included as part of the configuration process.

Table 5-4: Treatment Hierarchy by Distresses

Pavement Types:			
Flexible		Rigid	
Distress Indices:			
Overall Condition Index Non-Structural Distress Index Structural Distress Index		Overall Condition Index Slab Index Joint Index	
Distress Types:			
Fatigue Cracking Edge Cracking Patch Deterioration	Transverse Cracking Block Cracking Raveling	Slab Cracking Map Cracking	Joint Seal Damage Joint Spalling Faulting
Treatments:			
Do Nothing or No Maintenance Required Preservation: Surface Coats, Patches Resurfacing: Plant Mix Treatments (<0.15') Restoration: Plant Mix Treatments (>= 0.15') Rehabilitation: Recycling or Reclamation with Plant Mix Overlay Reconstruction: Remove and Replace		Do Nothing or No Maintenance Required Preservation: Grooving, Grinding and Sealing Resurfacing is not applicable to rigid pavements Restoration: Grind, Joint Seal, Slab Replacement Rehabilitation: Crack, Seat, and Overlay Reconstruction: Remove and Replace	

The following sections provide detailed discussion for configuration values that are being used.

Pavement Condition Data

In addition to pavement type, the distresses in Table 5-5 are collected and stored in the PMS. In addition, International Roughness Index (IRI) is captured by ITD and stored in inches/mile per FHWA *Highway Performance Monitoring System* (*HPMS) Field Manual*, 2010 or latest revision.

Table 5-5: Pavement Condition Distresses

Flexible	Rigid
Fatigue Cracking	Slab Cracking
Edge Cracking	Joint Seal Damage
Transverse Cracking	Joint Spalling
Raveling	Faulting
Block Cracking	Map cracking
Patch Deterioration	Studded tire ware
Rutting	

For all pavement types, the rules for defining the distresses, severity and extent ranges are determined by ITD for field data collection. For each survey section, distress and extent measurements are collected for three levels of severity: Low, Medium, and High. The extent range is continuous from zero to 100 percent. The definitions of Distress Severity shown below are defined per the Federal Highway Administration Publication No. FHWA-RD-03-031 *Distress Identification Manual for the Long-Term Pavement Performance Program*, June 2003, or latest revision. ITD distress data collection processing takes advantage of the automated data collection capabilities of the Pathways van currently owned and operated by ITD. With the more detailed data collection approach, the calculation of Individual Distress Indices allows the PMS to be configured to calculate the most accurate OCI. The reader is referred to the ITD PMS Configuration Document for detailed explanation of how existing conditions are measured and OCI is computed. The OCI is used to define the general health of the pavement section by combining the distress indices into a calculated value. It is also used for defining Benefit in the Optimization Analysis. The OCI is a calculated score that has been configured and is a significant divergence from the historic method for assigning Cracking Index subjectively to a pavement. It represents a much more defensible overall estimate of pavement health. For OCI, all distresses are combined in the calculation for each pavement type.

Treatments and Repair Categories

Treatments are the specific names defining the material and work that was applied at a location. These are typically found in Construction History and Master Work Plan data. However, Repair Categories are generally defined to represent Treatments of similar attributes for Optimization Analysis output. There is a relationship that exists in the PMS between Treatments, Work Codes, Pavement Type, and Performance Model Type. Performance Model Type is the performance class variable that identifies which models will be assigned when a treatment is applied.

Table 5-6: Repair Categories

Repair Category	Description
Do Nothing	No Maintenance Required
Preservation	Surface Coats, Patches Grooving, Grinding and Sealing
Resurfacing	Plant Mix Treatments (<0.15’)
Restoration	Plant Mix Treatments (>= 0.15’) Grind, Joint Seal, Slab Replacement
Rehabilitation	Recycling or Reclamation with Plant Mix Overlay, Crack, Seat, and Overlay
Reconstruction	Remove and Replace

Condition Index Improvement Rules

When a Treatment is selected in the Optimization Analysis, the deteriorating condition indices stored in the Network Master per management section is improved by a user specified amount. The PMS has been configured with the following condition indices and improvements when a Repair Category is selected.

Table 5-7: Flexible Pavement Improvement Rules

Condition Indices	Preservation	Resurfacing	Restoration	Rehab.	Recon.
Structural Distress Index	Add 5	Add 30	Add 50	Add 80	Reset to 100
Non-Structural Distress Index	Add 20	Add 50	Add 70	Reset to 100	Reset to 100
OCI	Add 15	Add 40	Add 60	Add 80	Reset to 100

Table 5-8: Rigid Pavement Improvement Rules

Condition Indices	Preservation	Restoration	Rehabilitation	Reconstruction
Slab Distress Index	Add 15	Add 30	Add 50	Reset to 100
Joint Distress Index	Add 20	Add 30	Add 50	Reset to 100
OCI	Add 20	Add 30	Add 50	Reset to 100

Supplemental Improvement Rules

Supplemental Improvement Rules are attribute values that do not deteriorate with time during the analysis but do reset based on the treatment that was selected. The PMS has been configured with the following improvements when a Repair Category is selected.

Table 5-9: Flexible Pavement Supplemental Improvement Rules

Improvement Variable	Preservation	Resurfacing	Restoration	Rehabilitation	Reconstruction
Performance Model Type	N/A	Set to Value	Set to Value	Set to Value	Set to Value
Pavement Age	N/A	Set to 0	Set to 0	Set to 0	Set to 0
IRI Average – in/mile	N/A	Set to 0	Set to 0	Set to 0	Set to 0
Rutting Medium – Percent	N/A	Set to 0	Set to 0	Set to 0	Set to 0
Rutting High - Percent	N/A	Set to 0	Set to 0	Set to 0	Set to 0

Table 5-10: Rigid Pavement Supplemental Improvement Rules

Improvement Variable	Preservation	Restoration	Rehabilitation	Reconstruction
Performance Model Type	N/A	Set to Value	Set to Value	Set to Value
Pavement Age	N/A	Set to 0	Set to 0	Set to 0
Map Cracking - Percent	N/A	Set to 0	Set to 0	Set to 0
Pavement Type Change	N/A	N/A	Change to Flex-ible	N/A
IRI Average - inch/mile	N/A	Set to 0	Set to 0	Set to 0
Studded Tire Wear Medium - Percent	N/A	Set to 0	Set to 0	Set to 0
Studded Tire Wear High - Percent	N/A	Set to 0	Set to 0	Set to 0
Faulting Medium - Percent	Set to 0	Set to 0	Set to 0	Set to 0
Faulting High - Percent	Set to 0	Set to 0	Set to 0	Set to 0

Treatment Priority and Exclusion Years/Priority

Each Treatment is assigned a Treatment Priority value. The priority value allows the system to choose a dominant Treatment when the analysis arrives at more than one possible Treatment solution. The analysis arrives at more than one Treatment solution when more than one Decision Tree is configured in the system for the management section's attributes.

Exclusion Years have been configured in the PMS window to require the analysis to wait a specified number of years before an equal or higher Exclusion Priority Treatment can be applied. Exclusion Priority Scores were taken as being equal to the Treatment Priority Scores because there was not a justification for making them different.

Table 5-11: Treatment Priority and Exclusion Year Priority

Repair Category	Treatment Priority	Exclusion Year Priority
Do Nothing	100	100
Preservation	300	300
Resurfacing	400	400
Restoration	500	500
Rehabilitation	600	600
Reconstruction	700	700

Exclusion years have been incorporated according to the following rules unless noted otherwise. Based on these rules and an initial modeling of deterioration model relationships, the following exclusion years have been configured.

Table 5-12: Flexible Pavement Treatment Exclusion Years

Repair Category	Exclusion Year
Do Nothing	N/A
Preservation	7
Resurfacing	10
Restoration	12
Rehabilitation	15
Reconstruction	20

Table 5-13: Rigid Pavement Treatment Exclusion Years.

Repair Category	Exclusion Year
Do Nothing	N/A
Preservation	10
Restoration	12
Rehabilitation	15
Reconstruction	30

Decision Tree Configuration

To ensure repeatability and consistency in the evaluation and selection process, Decision Trees have been developed and are used in the PMS to capture the decision-making rules necessary for the Optimization Analysis. There are two levels of trees, Upper and Lower. The Upper Level Trees streamline the configuration process by allowing similar node structures to be defined and reused for all Lower Level Trees. The Lower Level Trees consist of the detailed decision nodes structures necessary to trigger Treatments in the Optimization Analysis.

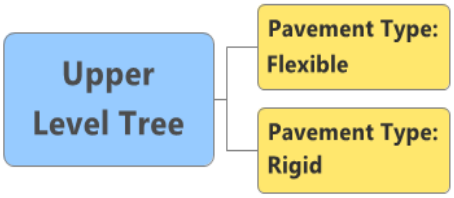

Figure 5-10: Upper Level Decision Tree Categories

Based on the Decision Tree Categories, multiple lower level trees were assigned to each pavement type. The lower level decision trees have been categorized based on Structural Distress Index, Non-structural Distress Index, Slab Distress Index, Joint Distress Index, IRI, and Rutting, shown in the following figures.

STIP Development

ITD's pavement management system is integral to the agency's pavement planning and programming. The model is used to estimate investment levels and investment types for each district both at the network and at the project level. Districts are given funding allocations and treatment allocations based on the model's recommendations. They balance those recommendations with engineering judgment of local conditions. Districts then develop a project-level set of projects for their district programs. Those projects are then modeled to ensure that the actual projects selected will allow ITD to achieve its pavement condition targets.

Bridges

Life Cycle Planning Process

ITD's practice for managing bridges and culverts is data-driven with expert mediation. The practice is data-driven because project selection and prioritization begin with Bridge Management System (BrM) data on structure conditions and work needs. It is expert-mediated because ITD staff in both central and district offices advance or delay specific work candidates based on knowledge of local needs together with global assessments of contributions to statewide mobility and system performance.

Two approaches are currently utilized in parallel at ITD to optimize the life cycle of bridges. The first approach uses an ITD developed Bridge Deterioration Model with a multi-objective optimization process developed over a number of years. Basic inventory and condition data from BrM are used in this process. The second approach also uses the same BrM data with planning modules inside the BrM software to predict future bridge deterioration, forecast future needs and identify recommended work candidates to

address needs. The in-house developed approach primarily drives decisions for projects that will be constructed in the next 1-7 years, which is the same time horizon of the Idaho Transportation Investment Program. Whereas the second approach, the planning modules of the BrM software, primarily drives decisions about investments needed 8-15 years into the future.

Recall from chapter 3, that 92 percent of all NHS bridges are on the SHS. ITD manages all of the SHS bridges and thus 92 percent of the NHS system using these two processes. ITD does not differentiate, prioritize or optimize the NHS or SHS bridges differently. They are all managed with the same underlying objective – to maximize service life for the lowest overall cost. While all bridges are managed with the same objective, it is important to acknowledge that these processes do tend to put more emphasis on Interstate bridges and other high traffic volume routes. In addition, generally higher traffic routes are on the NHS.

Bridge Management System

ITD uses the Bridge Management System (BrM) which is developed by the American Association of State Highway and Transportation Officials (AASHTO). ITD uses BrM to store inventory data, condition data, and inspectors' recommended work candidates.

The first step in Life Cycle Planning is for ITD Bridge subject matter experts to examine BrM data for all bridge conditions, age and truck weight capacity in order to group assets into good, fair, and poor performance categories, as shown in Figure 2-2 and Figure 2-4 shown in chapter 2. These groupings facilitate making general high-level observations of entire networks (such as the SHS or NHS). From this, observations are made about global changes in system performance along with beginning the process to identify specific low performing bridge assets that may be a hindrance to the route or network's performance. For example, a load posted bridge in poor condition on a route that otherwise contains fair to good conditions bridges capable of carrying legal truck loads is a low performer that is affecting the service of a segment of a route. Depending on where this route is between destinations, proximity of suitable of a detour route and other factors will influence how high a priority it is to be addressed.

ITD Bridge Deterioration Model and Multi-Objective Optimization Process

Using historical Idaho National Bridge Inventory (NBI) condition data from the last 25 years, ITD has developed an in-house bridge deterioration model similar to any basic asset management model. The ITD bridge deterioration model is based on the entirety of the state bridge system not individual bridges and is primarily used to drive investment decisions for the time horizon of the Idaho Transportation Investment Program (ITIP) which are the next 1-7 years in the future. The amount of square footage area of bridge that becomes deficient every year (approximately 90,000 square foot assuming a severe deterioration rate) drives the model. Historically deterioration varies by yearly weather conditions, deicing chemical usage, and our aging bridge population. To account for bridge deterioration modeling inaccuracies the model assumes a benign, moderate and severe deterioration. Bridge replacement project candidates are chosen and evaluated in order to build the list of projects in the ITIP with respect to a set amount of funding. This is done with the primary objective to move ITD's bridge performance measure from 75 percent to 80 percent of bridge deck square footage area to be in a "State or Good Repair" or "Good" Condition.

Prioritizing individual bridges for the Bridge Preservation and Bridge Restoration Programs involves using a multi-objective optimization process. The optimization process considers bridge condition, age, design load capacity, life cycle cost accounting, bridge preservation vs. replacement cost, ADT, route designation, scour and seismic vulnerability, and many other factors. The multi-objective optimization process involves selecting and prioritizing candidates that maximizes the number of criteria matches, but also takes into account project budget size for the available funding. The criterion is in no particular order and is not weighted one over another.

Table 5-14: Multi-Objective Variables

Bridge Parameter	Consideration
Bridge Age	Consider replacement if greater than 50 years old
Overload Permit Capacity and Annual Trip Routing	Consider replacing bridges on routes that restrict commercial truck traffic
Bridge Condition	Consider replacement of bridges with NBI ratings of 5 or less
Scour Critical Rating	Consider replacing bridges with that are scour critical
Weight Posted Bridges	Consider replacing bridges with legal weight postings
Seismic Vulnerability	Consider replacement of bridges in high seismic areas or retrofit need
Overhead Clearance	Consider replacement if overhead clearance is less than 16’
Bridge Width	Consider replacement if width is functionally obsolete
Review Element Condition States	Consider replacement if large percentages are in Condition State 3
Design Vehicle	Consider replacement if design vehicle less than HS-20
Route and ADT	Consider higher replacement priority for bridges on the Interstates and high ADT routes
Life Cycle Cost Analysis	Consider replacement where rehabilitation costs exceed 50% of new bridge cost
Benefit/Cost Ratio	Consider replacement based on higher B/C ratio from BrM
Project Budget	Consider project budget size for best fit for Bridge funding
Bridge Performance Measure	Consider projects that move bridge condition measure upward

While ITD's Bridge Condition Performance measure is primarily driven by bridge condition, other functional aspects of bridges are taken into account through the multi-objective optimization process. When bridges are replaced in the Bridge Restoration program, they are modernized to appropriate design standards and take into account other modes of traffic such as accommodation for pedestrian, bicyclist and future light rail compatibility as appropriate.

Deterioration Forecasting and Prioritization

In addition to using the ITD Bridge Deterioration Model and multi-objective optimization process described above, ITD also uses planning modules within BrM to perform bridge deterioration modeling, forecasting future conditions, and investment scenario optimization. This second method uses algorithms, decision trees, utility profiles and deterioration rates that are built into the BrM software with some customization by ITD. Decision trees, and to some extent algorithms, have been customized by Bridge staff to align with the business practices and policies of ITD. Deterioration rate curves have been derived from analysis of years of historical ITD bridge data.

All of the information fed into BrM is used to model future conditions on bridges. Recall, the BrM software is primarily used to model conditions well into the future beyond the seven year horizon of the Idaho Transportation Investment Program. BrM identifies and quantifies bridge needs for 8-15 years into the future and drives overall investment planning levels, not individual project selection for that time horizon. BrM makes predictions about future bridge performance levels based on several funding scenarios. High, medium and low funding scenarios are run. Medium is considered maintaining current funding levels. High and low levels represent an increase and a decrease in funding levels respectively. All of this information is reviewed by Bridge staff to ascertain optimal investment levels for the time period just beyond the Idaho Transportation Investment Program, 8-15 years into the future.

Planning this far into the future helps ITD to manage bridge performance through uncertain funding levels, economic cycles, variable environment (weather) patterns which have some influence on how fast bridges deteriorate, and cost increases and volatility in the highway construction market sector. Currently the BrM software is used as planning tool for ITD. The modules described above are relatively new when compared to the inspection data collection and storage modules. ITD in partnership with the software developer, AASHTOware has committed to further enhance the accuracy of this planning tool. This work is described in more detail in the "Additional Process Improvements" section in Chapter 4.

Synthesizing Results and Developing the Bridge Programs

Using the information from ITD's in-house Bridge Deterioration Model, BrM condition data, and output from BrM planning modules, subject matter experts in Bridge develop a draft list of best value investments for the SHS bridges. These investments are developed or scoped at a planning level into projects and grouped into similar work programs of restoration and preservation work. This information is reviewed jointly by ITD staff in the central office and in district offices. As buildable projects emerge, staff from the central office and district offices collaboratively develop the final list of projects for the Bridge Restoration and Bridge Preservation programs. Some consideration is given to reasonably balance programs across the state.

The final work programs for Bridge Preservation and Bridge Restoration are established with consideration to yearly funding levels set by the ITD Board. Increased funding over the past few years has enabled ITD to invest in improving an increasing amount (when compared to historical levels) of bridge deck area from deficient to "Good "condition or to a "State of Good Repair". The amount of improving deck area has been greater than the amount of deck area that is declining. This shift from deficient to a State of Good Repair is the basis for a positive trend in ITD's SHS Bridge performance measure as well as the Federal Bridge Performance Measure for the NHS.

Figure 5-21, is a high-level schematic overview of how bridge performance data is acquired, utilized, and reviewed in concert with the development the Idaho Transportation Investment Program (ITIP).

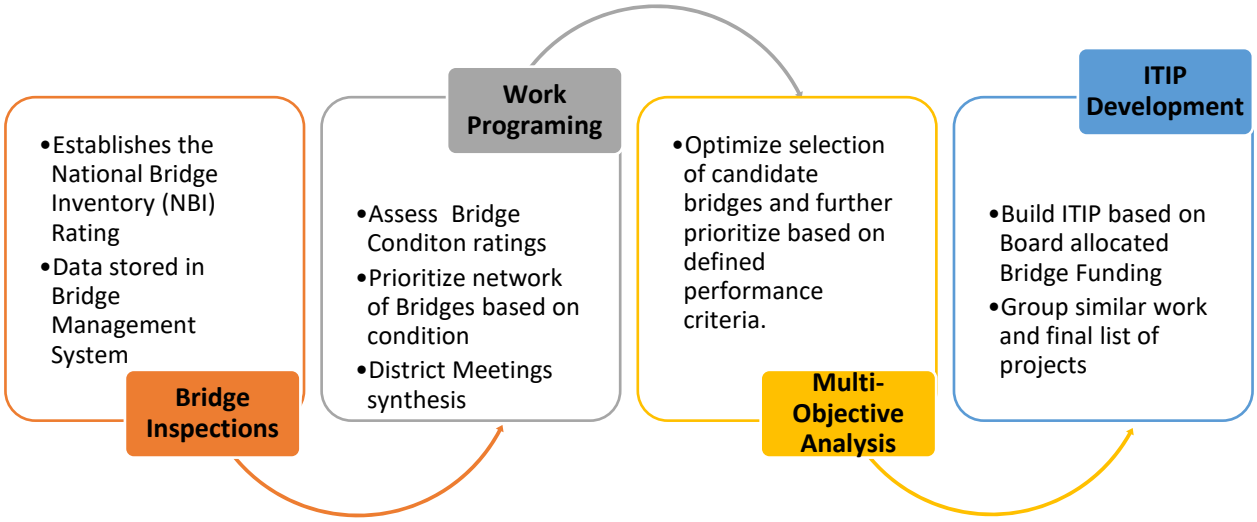

Figure 5-21: Bridge Lifecycle Data Flow

It is important to note that the bridge programs that ITD uses to address bridge deficiencies are project oriented and include all project costs such as approach roadway work and other ancillary highway work such as traffic control, drainage, and/or lighting. For example, Interstate System Interchange projects that include bridges can be and are programed in the Bridge Restoration Program at times. Funding on these larger and complex projects to address bridge deficiencies may be less than one-half the total project cost.

Bridge Life Cycle Strategy

ITD's goal in using Bridge Preservation and Restoration programs and a life cycle planning process is to maximize a bridge's utility while simultaneously minimizing costs (investments) over the bridge's service life, usually 75 plus years. See Table 5-15 below for lifecycle planning objectives and strategies employed by ITD. Typically, after initial construction of a bridge and its subsequent opening to the public, cyclic maintenance is programmed for the bridge in order to maintain it in "Good" condition. Protective deck overlays, joint replacements, and painting are examples of cyclic maintenance. Sometimes as the bridge ages, more extensive bridge rehabilitation or repairs are necessary such as deck overlay or complete deck replacement.

These strategies show that ITD is moving toward managing bridges with the lowest lifecycle cost, although financial constraints and other uncertainties such as increasing heavy truck loads, increasing use of deicing

chemicals, changes in the construction market, unexpected extreme events, and other factors make finding the overall lowest life cycle cost across all bridges on the SHS a constantly moving target.

Table 5-15: Bridge Preservation Lifecycle Planning Objectives and Strategies

Objectives	Strategies
Extend the Service Life of our Bridges, Keep Good Condition Bridges in Good Condition	Move away from bare deck strategy, Provide Deck Protective Systems, Program cyclic maintenance and bridge preservation projects
Life Cycle Cost Analysis	Optimize repair strategies and materials using life cycle cost analysis.
High Priority Repair Projects	Program and designate high priority projects for unique repairs
Maximize Bridge Budget-Bundle candidate bridges and repair treatments into efficient contracts	Group like preservation treatments for multiple bridges for economy of scale
Evaluate Painting or Protective Coating Needs on a cyclic basis	Forecast potential needs in advance for inclusion into projects

Environmental Conditions & Risk Considerations

The State of Idaho has a broad range of climate regions in which bridges are located. From dry, semi-arid desert regions in the south, to mountainous regions throughout much of the state where heavy snowfall and winter conditions are common, to wet-riverine environments in the valleys where occasional flooding and debris flow occurs during wetter years, it is clear that this diversity influences bridge service life and performance. ITD considers climatic factors and their deterioration severity through use of service environments in its BrM deterioration modeling. Service environments consider exposure to things such as freeze/thaw cycles, deicing salt exposure, or debris impact and scour on bridge elements. These service environments help ITD to consider the deterioration of a bridge due to environmental factors and prioritize actions based on life cycle cost analysis and best change in utility.

Benefit/Cost Ratios

ITD'S Bridge Management Program, BrM, can demonstrate the value of investing or performing work on a bridge. Work can be as extensive as total replacement or more minor in nature, such as doing work to maintain or preserve the current condition of a bridge. BrM evaluates investments by considering the benefit doing work provides to the condition and utility and usefulness of a bridge in relation to the cost (the investment) that work requires. This evaluation is expressed as a benefit/cost ratio. The value of the ratio increases as the benefits of doing some work exceed the cost to do it.

For example, a bridge has two possible work actions that could be done but there is only sufficient funding to do one of the work actions. Action A costs twice as much as action B but both accomplish the same thing, fixing a deck with cracks and potholes. In this simplistic example, action B would be chosen because it provides a benefit in the form of a smooth riding bridge deck that will not continue to deteriorate into

an unsafe condition for half the cost of action A. Action B's benefit/cost (B/C) ratio is two, while action A's B/C ratio is one. The expected service life of either action A or B is not considered in this simplistic example.

Right Investment at the Right Time

As bridges age, carry traffic, are exposed to weather such as freeze/thaw cycles, and periodically experience unexpected extreme events such as a flood, they deteriorate. Every new bridge starts its life in excellent condition and slowly begins a decline to poor condition. ITD makes investments periodically throughout a bridge's life to slow this inevitable decline. Using its staff's subject matter expertise of all the available investment types or treatments along with recommendations from BrM, ITD makes decisions about what treatment(s) are the best fit for the problem(s) facing a bridge. This analysis is done at several levels. First, it is done at a high-level, system wide for many bridges to determine the optimal balance of preservation versus restoration of bridges with respect to the amount of transportation funding available. The next section will discuss this in greater detail.

Once preservation and restoration program budgets are set, ITD HQ bridge staff, using information from BrM and their knowledge of effective treatments, consult with district staff to determine what bridges need what treatments. For example, some possible treatments could be epoxy deck sealing, concrete overlay, replacing leaking expansion joints, fiber wrapping damaged girders, or installing countermeasures to arrest scour in a riverbed. ITD's objective is to apply the most appropriate and cost effective treatment to address the problem(s) on the bridge. A range of investments is considered. Using principles of life cycle planning, often times treatments that have a higher initial cost than other treatments but last substantially longer are chosen because they are cheaper and more cost effective when looking at the entire life span and costs incurred to operate a bridge for 75 plus years.

In addition to applying the right treatment, applying the treatment at the right time is the other cornerstone to good life cycle planning. For example, painting a steel bridge at the right time is highly effective in prolonging its life. However, if painting is delayed, at some point, too much of the steel is eaten away by rust, painting is no longer effective, and a much more expensive rehabilitation or replacement action is required. ITD bridge staff generally follow typical industry bridge maintenance schedules as a starting point to time investments. Then using information from BrM, they adjust either up or down the specific year investments are made on a given bridge in response to how fast deterioration is occurring on the bridge. Deterioration may be more severe or mild than expected due to a variety of factors. Such as a series of harsh winters and the subsequent heavier than normal use of deicing chemicals on a bridge deck would cause it to deteriorate faster than normal. Other factors affect timing of investments such as cost volatility in construction markets or the possibility to bundle similar work on other bridges in an area to achieve savings from increasing economies of scale.

Finally four times a year, Bridge staff share minor maintenance and preservation needs with the districts. Districts primarily complete this minor work with their own forces. This type of work extends the life of bridge and stops minor problems from developing into bigger more costly problems. This work includes activities such as minor spot repairs, deck sweeping, expansion joint cleaning/repair, and gutter and drain cleanout.

Investing in Preservation vs Restoration Work

ITD has funding dedicated to Bridge Preservation and to Bridge Restoration programs. These dedicated funding programs are integral to ITD's focus on improving performance of bridges. Preservation and restoration, together, have allowed ITD to shift away from a worst first approach to best value work programming. To achieve this shift, ITD staff analyzed the outcome of bridge conditions that would result from several different funding splits between bridge preservation and restoration.

In the analysis, bridge conditions were related to age. Costs for preservation and restoration projects were expressed in terms of bridge deck area. As mentioned, several budget levels were investigated. Greater or lesser budgets delivered preservation and restoration at greater or lesser aggregate quantity of bridge deck area. The analysis showed that funding directed to a mix of preservation and restoration projects would lead to better conditions across all SHS bridges. The result of the study set ITD's current strategy for managing SHS bridges and culverts. ITD's management strategy directs approximately 20 percent of funding to Bridge Preservation and 80 percent of funding to Bridge Restoration. With 75 percent of bridges in a state of good repair and a target to be at 80 percent in a state of good repair, this 80/20 balance between restoration and preservation is optimal. As bridge conditions improve, as they are forecasted to do, ITD will reevaluate this balance and determine if there is more optimal balance in how funds are split between restoration and preservation when the performance targets are achieved and the gaps are closed.

As mentioned, ITD currently directs approximately 20 percent of its bridge funding to preservation and 80 percent to restoration. Investing in bridge preservation keeps our "Good" bridges in "Good" condition and flattens the rate of bridge deterioration that normally occurs over time. Companioned with this is an 80 percent funding allocation to restoration work. This work takes bridges in poor condition and returns them to good condition. Most of the time this is through replacement of poor, obsolete, and restricted bridges with new bridges in excellent condition capable of carrying modern heavy vehicles loads. Some bridges are restored through rehabilitation work. Such as a bridge with a deck in poor condition and girders in fair-to-good condition. The optimal investment type for this bridge may be to replace the deck only and do spot repairs on the girders and foundation. The current 80/20 split coupled with an $80M per year investment in bridgework overall is sustainable with given funding. As shown in chapter 3, Figure 3-17, given the current funding level, this split shows ITD will meet its performance target and close the current performance gap in about 5 years.

When the performance target is achieved, investing a larger percentage of bridge funds in preservation may be optimal in the future. However, for the current conditions, as ITD strives to reach our bridge performance target, with given funding levels, the 80/20 split in bridge funding is appropriate.

Bridge Preservation

Project selection for the Bridge Preservation Program centers on keeping our bridges that are in "Good" condition in "Good" Condition. Project selection is not necessarily condition based, but with more of a focus on cyclic maintenance and preserving current conditions. Candidate selection emphasizes similarity of preservation treatments amongst groupings of bridges in an area while applying the right treatment at the right time for optimal cost effectiveness. Another way to look at the Bridge Preservation program at

ITD is that with the yearly 20 percent investment of Bridge Program dollars into preservation approximately 1,000,000 sq. ft. of bridge deck area in "Good" Condition are maintained in "Good Condition".

Cyclic maintenance in Bridge Preservation projects involve activities performed roughly at predetermined intervals to maintain current conditions on bridges. Following these intervals and implementing these activities will delay deterioration. ITD strives to implement deck protective systems within one to three years after original construction is complete. Depending on a bridge's condition and the type of treatment chosen ITD expects to reapply the treatment on a 10 to 30-year cycle. See Table 5-17 for an illustration of a preservation life cycle planning approach. While the ITD preservation strategy requires more treatments to be undertaken though out the life cycle of the structure, the costs are much lower than doing nothing for many years and then implementing fewer but much more costly treatments to maintain a bridge. This is illustrated in Figure 5-22: Comparison of Restoration vs Preservation Cumulative Lifecycle Costs shown on page 5-32. It can be seen that the cumulative net present value of the preservation strategy saves $161 per square foot of deck over the life of the structure as compared to the rehabilitation strategy.

It is important to note that preserving a bridge in good condition in most cases will not show a high value benefit/cost ratio, as there most likely will be no change in the condition of the bridge deck. However, over time and with our deterioration modeling, a positive benefit/cost ratio is shown as the bridge deck condition would have deteriorated without the benefit of the bridge preservation treatment. Running multiple modeling scenarios using different funding splits for perseveration and restoration show high value positive benefit/cost ratios because decline in condition is delayed with relatively low cost bridge preservation treatments in comparison to more costly rehabilitation or replacement actions.

Cyclic Bridge Preservation

As another example of ITD's life cycle planning approach is how we determine the right action or investment at the right time. Typically, when a new bridge is constructed a protective bridge deck overlay will be installed within approximately one to three years after it is opened to traffic. The selection of the type of protective overlay is dependent on route, ADT and cost. For lower ADT routes, many times a protective overlay applied on a cyclic schedule can prove to have a high cost benefit ratio. On the other hand, for high traffic routes like the Interstates a more costly but longer lasting more durable protective overlay proves to be more cost effective over the life of the bridge considering the high traffic these bridges tend to carry, the high cost to control traffic during installation, the associated safety concerns on these high speed bridges, the high traffic volumes on these routes and the impact or user costs to the public if these were bridges under more frequent construction installing cheaper, less durable treatments.

Further, ITD's life cycle cost analysis takes into consideration other typical maintenance activities such as joint or bearing work and application of other protective coatings. The initial costs of these activities and the estimated life of these activities are considered. The objective is to time these other activities with the next cyclic application or bridge preservation activity takes place to realize savings in administering construction contracts and contractor costs mobilizing to a bridge site to do work.

Table 5-16: Rehabilitation Strategy Life Cycle Planning Costs

Rehabilitation Strategy		
Year	Activity	Cost (ft^2)
0	New Construction	$200
20	Deck Rehabilitation	$20
	Joint Replacement	$2
40	Deck Replacement	$100
60	Deck Rehabilitation (Hydro & Silica Fume Over-lay)	$20
	Joint Replacement	$2
80	Deck Replacement	$100
100	Replace Bridge	
Net Present Value		**$444**

Table 5-17: Preservation Strategy Life Cycle Planning Costs

Preservation Strategy		
Year	Activity	Cost(ft^2)
0	New Construction	$200
1	Thin Overlay	$5
10	Thin Overlay	$5
20	Thin Overlay	$5
	Joint Replacement	$2
30	Thin Overlay	$5
40	Deck Rehabilitation (Hydro & Silica Fume Over-lay)	$20
	Joint Replacement	$2
50	Thin Overlay	$5
60	Thin Overlay	$5
	Joint Replacement	$2
70	Thin Overlay	$5
80	Deck Rehabilitation	$20
	Joint Replacement	$2
100	Replace Bridge	
Net Present Value		**$283**

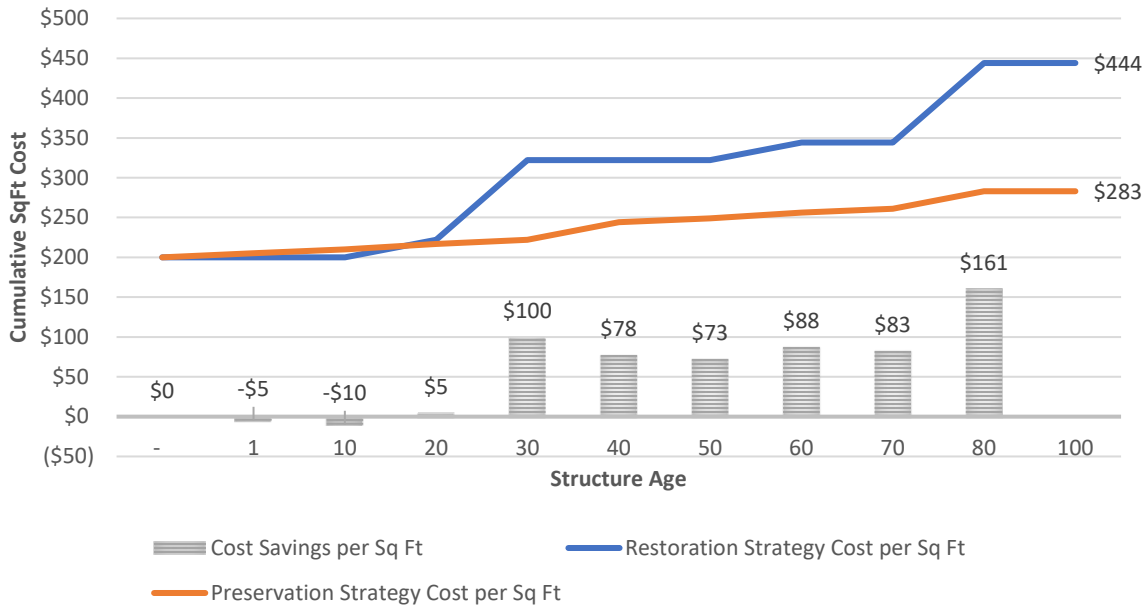

Figure 5-22: Comparison of Restoration vs Preservation Cumulative Lifecycle Costs

Bridge Restoration

Project selection for the Bridge Restoration Program centers on taking bridges that are in Poor condition and returning them to Good Condition. Project selection is primarily condition based, with additional emphasis on age, restriction on freight or truck traffic, susceptibility to extreme events e.g. earthquake or flood. Consistent with the multi-objective optimization process described earlier, other factors can also influence project selection such as route importance, traffic volume, and width/lane restrictions.

Figure 5-23: Example of Poor Condition Bridge Deck

Currently 80 percent of ITD's bridge funding is devoted to this program. As described in Chapter 3, ITD is on a multi-year endeavor to increase the percentage of bridge deck area in "good" condition from 75 percent to 80 percent on the SHS. To achieve this 5 percent gain, a substantial investment is needed over several consecutive years to replace or rehabilitate poor condition bridges. The specific dollar amount invested fluctuates somewhat from year to year, but on average ITD is spending $60-65 million every year on this program to get rid of old, obsolete and poor condition bridges. Another way to look at the Bridge Restoration program at ITD is that with the yearly investment of $60-65 million, approximately 100,000 sq. ft. of bridge deck area is improved from poor condition to good condition.

It is important to note that ITD includes all costs of a project in the funding category listed in the Idaho Transportation Investment Program. This point is especially important in the Bridge Restoration program. Often Bridge Restoration projects, especially those replacing poor bridges with new ones include some portion of approach roadway work on either end of the bridge. While the Bridge Restoration program's primary objective is to address deficiencies on poor condition bridges, many other non-bridge costs may be included in a given project in this program depending on specific project constraints and scope. For example, poor condition bridges that are being replaced within an Interstate System Interchange can be programed in the Bridge Restoration Program. The funding needed to address only bridge deficiencies

may be far less than one-half the total project cost due to all the approach roadway work adjustments often needed in modernizing a freeway system interchange. ITD accounts for additional non-bridge costs by assigning a cost multiplier to certain Bridge Restoration projects it is considering undertaking.

Chapter 6 - Risk Management Process

ITD has adopted an on-going process to identify, assess, and manage its major risks, including those that could affect its asset management objectives, strategies, and achievement of its targets.

ITD adopted for this asset management risk analysis the Federal definition of risk, which is the positive or negative effects of uncertainty upon agency objectives.

Any plan as long-term and ambitious as an asset management plan faces many uncertainties. The plan requires the forecasting of revenues, the prediction of pavement and bridge performance, assumptions about traffic growth and climate, and assumptions that economic and political priorities will remain stable. Major changes in revenues, political priorities, or agency policies could prevent any of the objectives or targets in this plan from being met.

This risk chapter acknowledges many risks that could affect the plan and describes how ITD plans to manage those risks.

Risk Analysis Requirements

In Sec. 515.7 (c) of the final rule, FHWA says, "A State DOT shall establish a process for developing a risk management plan. This process shall, at a minimum, produce the following information:

(1) Identification of risks that can affect condition of NHS pavements and bridges and the performance of the NHS, including risks associated with current and future environmental conditions, such as extreme weather events, climate change, seismic activity, and risks related to recurring damage and costs as identified through the evaluation of facilities repeated damaged by emergency events carried out under part 667 of this title. Examples of other risk categories include financial risks such as budget uncertainty; operational risks such as asset failure; and strategic risks such as environmental compliance.

(2) An assessment of the identified risks in terms of the likelihood of their occurrence and their impact and consequence if they do occur;

(3) An evaluation and prioritization of the identified risks;

(4) A mitigation plan for addressing the top priority risks;

(5) An approach for monitoring the top priority risks; and

(6) A summary of the evaluations of facilities repeatedly damaged by emergency events carried out under part 667 of this title that discusses, at a minimum, the results relating to the State's NHS pavements and bridges.

Identify Objectives and Risks

In Chapter 1, ITD identified its asset management objectives and targets. The objectives are to:

1. Reduce Fatalities
2. Maintain the Pavement in Good or Fair Condition
3. Maintain the Bridges in Good or Fair Condition
4. Keep Highways Clear of Snow and Ice During Winter Storms
5. Hold Administration and Planning Expenditures Constant

6. Complete Project Designs On Time
7. Hold Construction Cost at Award to Programmed Budget
8. Hold Final Construction Cost to Contract Award

The targets are to:

- Allow no more than four percent of Interstate pavements to be in poor condition
- Keep 50 percent of Interstate pavements in good condition
- Allow no more than eight percent of Non-Interstate NHS pavements to be in poor condition
- Keep 50 percent of Non-Interstate NHS pavements in good condition
- Allow no more than three percent of NHS bridges to be in poor condition
- Keep at least 19 percent of NHS bridges in good condition

ITD already had adopted an Enterprise Risk Management (ERM) process. Senior executives met with all districts and divisions to identify risks that could affect the department's major strategic objectives. Subsequent to the ERM assessment, a separate meeting was held to specifically identify risks to the asset management objectives, assess the risks, and identify mitigation strategies. The asset management risks and the mitigation to them will be managed to reduce their negative impacts and enhance their positive ones.

Identification and Assessment of Risks

The risk management process focused upon the issues, events, or trends that could affect achievement of the asset management objectives. Senior agency leaders reviewed the agency's objectives and then systematically considered different categories of risks that could impede those objectives. Risks were recorded as "if/then" statements such as, "If Federal funding decreases, then ITD may not be able to sustain its assets in a state of good repair." Forty-one risk statements were captured as final risks after several others were discarded as redundant or irrelevant to asset management.

Each potential risk was recorded by the leadership and then assessed with the risk matrix seen in Figure 6-1. The risk exercise participants were led through an assessment of each risk by its likelihood and impact resulting in an overall risk rating. The risk matrix included standard definitions for the level of likelihood and impact. When the likelihood and impact were both considered, the risk rating could be identified. As seen in Figure 6-1, the risk rating is a function of likelihood times impact and ranges from insignificant to very significant.

Major Risks

In the risk registers seen below, the most significant risks are highlighted in red. Among the most serious risks were issues such as uncertain Federal funding, changing Federal priorities, future changes in Idaho priorities that could diminish a focus upon managing assets, population growth that creates additional demand for congestion-relief projects. The major risks illustrate the uncertainty surrounding key plan assumptions. The plan assumes that revenues will remain predictable, that construction prices will not increase excessively, and that public policy will continue to prioritize the management of assets. Changes in those conditions could impede the achievement of the plan's objectives and lead to failure to sustain the condition targets.

Monitoring Approach

ITD's senior leadership will monitor these risks and keep abreast of changes to the risk ratings. ITD's existing process includes senior executives monitoring the risks and reporting changes to them. The senior staff can then take steps to address the risks if they arise.

Risk Matrix with Impact and Likelihood Definitions			Likelihood				
			Rare	Unlikely	Possible	Likely	Very Likely
		For Recurring Events	Less than once in 5 years	Once in 5 years	Once in 3 years	Once per year	More than once per year
		For Single Events Probability over 5 years	< 10% (Less than 1 in 10)	10% to 25% (Avg. of about 1 in 6)	25% to 40% (Avg. of about 1 in 3)	40% to 60% (Avg. of about 1 in 2)	> 60% (Avg. of about 4 in 5)
Impact	Very Significant	Multiple deaths & injuries, substantial public and private cost, and/or Governor or Legislature "takes over" ITD (e.g., change in Director, disabling legislation). .	Medium	Medium	**High**	Very High	Very High
	Major	Multiple injuries, or a single death, substantial public or private cost and/or foils agency objectives.	Low	Medium	**High**	**High**	Very High
	Moderate	Injury, property damage, increased agency cost and/or impedes agency objectives.	Low	Medium	Medium	**High**	**High**
	Minor	Moderate agency cost and impact to agency objectives.	Low	Low	Low	Medium	Medium
	Insignificant	Impact low and manageable with normal agency practices.	Low	Low	Low	Low	Medium

Figure 6-1: Risk Matrix Used for the Asset Management Risk Assessment

Part 667 Assets

23 U.S.C. Part 667 carries out a provision of the Fixing America's Surface Transportation Act (FAST Act). That section requires states to identify and evaluate roadway assets subject to repeated damage during emergencies. FHWA requires the asset management plan to acknowledge these assets and discuss them in the risk management plan, if such assets exist in the state. FHWA promulgated in the final asset management rule a narrow approach to this section. States need to identify NHS assets that have been substantially damaged two or more times during officially declared emergencies since Jan. 1, 1997. The plan does not require the States to identify repair or mitigation strategies for these assets. Instead, they are to be considered in the normal programming process, at the State's discretion.

ITD Emergency Fund Coordinator performed an evaluation for all declared emergencies 1997- 2019 affecting NHS facilities in Idaho. No locations meeting the criteria of 23 U.S.C. Part 667 were identified. A completed listing of these events is provided.

Risk Registers

The risk registers developed for this asset management plan are as follows. The tables summarize the risks that were identified and assessed. Risk responses are included for each. These risk registers will be incorporated and updated as part of ITD's ongoing enterprise risk management program.

RISK #	Objective	Maintain Assets in a State of Good Repair				
	Risk Event	Risk Effect	Likelihood	Impact	Rating	Response
R1	If MPO project selection does not emphasis asset management…	...then more emphasis could be given to new-capacity projects at the expense of maintaining asset conditions.	Possible	Moderate	Medium	ITD will continue to emphasize to MPOs and other stakeholders the importance of maintaining good asset conditions.
R2	If Federal funding decreases..	…then ITD may not be able to sustain its assets in a state of good repair.	Very Likely	Major	Very High	ITD will monitor Congressional actions on Federal-aid apppropriations and remain in contact with the Congressional delegation to emphasize the importance of Federal-aid to the ITD program.
R3	If program selection priorities do not emphasize sustaining asset conditions…	..then ITD may not be able to invest appropriately to sustain a state of good repair.	Likely	Moderate	High	ITD will urge legislators to continue giving high priority to ITD recommendations for bridge and pavement investments to ensure that programs to preserve asset conditions remain a top prioritiy.
R4	If changing Federal Rules consume more ITD resources….	…ITD may not be able to sustain adequate investments to maintain a state of good repair.	Likely	Moderate	High	ITD will monitor Federal rule making and encourage Federal agencies and Congress to not adopt new burdensome rules that could increase the cost of delivering projects or maintenance activities.
R5	If population growth and land uses increase creating high demand for congestion-relief projects…	..then ITD may not be able to invest enough to sustain a state of good repair.	Likely	Moderate	High	ITD will remain active in the metropolitan and statewide planning processes to monitor population and traffic growth and advise the Board if the demand for new capacity projects exceeds current amounts budgeted for them.
R6	If ITD priorities change and de-emphasize maintaining asset conditions….	…then the department's investments in bridges and pavements could decrease and it will not sustain a state of good repair.	Low	Major	Low	ITD leadership remains committed to asset management.
R7	If ITD leadership changes direction the support for maintain assets could diminish…	…then we may not sustain a state of good repair.	Low	Major	Low	ITD leadership remains committed to asset management.
R8	If land Use predictions are not accurate…	…then will not accurately predict travel demand and the need for congestion-relief projects.	Likely	Moderate	High	Planning staff will continue using best available data and modeling to forecast travel demand.

Figure 6-2: Risks to Maintaining Assets in a State of Good Repair

	Objective	Maintain Pavements in a State of Good Repair				
R9	**Risk Event**	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R10	If the quality of recycled asphalt and other materials is not maintained to a high standard …..	…then we will not sustain our pavements in a state of good repair.	Possible	Minor	Low	ITD will remain diligent about materials testing and acceptance to ensure high-quality pavements.
R11	If we over-rely on surface treatments …	… then we could have inaccurately high pavement-condition readings and lead to a false sense of confidence in the longevity or our pavements.	Possible	Minor	Low	ITD will remain committed to a well-balanced treatment program that applies the appropriate treatment based upon pavement conditions and funding availability.
R12	If the pavement management system is improved…	…then we could have a significant opportunity to enhance our modeling of pavement conditions.	Likely	Moderate/ Major	High	ITD will push ahead with acquiring a new pavement management system or improving the current one. A high-functioning pavement management system provides a significant opportunity to better manage pavements.
R13	If we do not have adequate contractor availability…	…then we will face higher prices and inability to deliver projects where and when we need them.	Likely	Minor	Medium	ITD will monitor the number of contracts and bids, and advise the Board and agency leadership if a lack of competition could influence bid prices and leader to higher-than-expected prices.
R14	If ITD and the contractor community does not adapt to performance-based specifications….	… then we will not get the pavement quality that we need.	Likely	Moderate	High	ITD will continue training staff and engaging with contractors to successfully implement performance specifications.

Figure 6-3: Risks Specific to Maintaining Pavements in a State of Good Repair

	Objective	Sustain Adequate Funding for a State of Good Repair				
	Risk Event	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R15	If the donor/donee state financial balance is changed…	…then it could result in ITD receiving less Federal revenue.	Possible	Very Signficant	High	ITD will continue coordinating with Idaho's Congressional delegation to preserve Idaho's donee state status.
R16	If there is Congressional uncertainty over the state of the Highway Trust Fund…	…then it could result in ITD receiving less Federal revenue.	Possible	Moderate	Medium	ITD will monitor Congressional actions on Federal-aid apppropriations and remain in contact with the Congressional delegation to emphasize the importance of Federal-aid to the ITD program.
R17	If there continues to be changing vehicle mix and reduced fuel consumption…	…then State and Federal revenues could continue to decline.	Likely	Minor	Medium	ITD will monitor tax receipts and advise the Board if trends will result in revenues that fall below expectations.
R18	If construction inflation increases signficantly….	…then our purchasing power will fall and we will not be able to sustain a state of good repair.	Rare	Moderate	Low	ITD will monitor bid prices for price increases that exceed those that are expected.
R19	If labor costs increase or ITD experiences a shortage of skilled workers..	…then our costs will increase or we will not be able to achieve the performance we need.	Possible	Moderate	Medium	ITD will monitor bid prices for price increases that exceed those that are expected.

Figure 6-4: Risks to Sustaining Adequate Investments for a State of Good Repair

	Objective	Maintain Structures in a State of Good Repair				
	Risk Event	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R20	If we experience increasingly harsh winters and sustained salt use…	…then our bridges will sustain increased deterioration.	Possible	Moderate	Medium	ITD will contiue its bridge preservation efforts to reduce the impact of winter chemicals.
R21	If we receive conistent funding at current levels…	…then we will not be able to repair or replace the wave of aging bridges that are coming.	Likely	Moderate	High	ITD will continue its bridge preservation and rehabilitatio efforts to maintain aging bridges and slow their deterioration rate. ITD also will monitor the bridge inventory closely and advise the Board of long-term investments needs to address our aging inventory.
R22	If the traffic volumes and truck weights continue to increase…	…then our bridges will sustain increased deterioration.	Possible	Major	High	ITD will monitor truck weights and advise the Board if excessive truck weights become a factor on bridge condition.
R23	If contractor workmanship is not adequate…	…then we will not get the quality of construction that we need to sustain our bridges.	Possible	Moderate	Medium	ITD will maintain its diligence on contractor performance and material quality.
R24	If we don't develop task order contracts for cyclic maintenance contracts…	..then it will be difficult to respond quickly to timely maintenance needs.	Possible	Minor	Low	ITD will explore the expansion of task order contracts to provide cyclic maintenance.
R25	If we don't develop a program to address our large structures that will need rehabilitation or replacement in the next decade…	…then our conditions will decline or we will have to divert all bridge funds to only a few structures for several years.	Very Likely	Major	Very High	ITD will develop a multi-decade plan for when its high-cost large structures need to be rehabilitated or replaced and will attempt to fund a program to address them.
R26	If we don't maintain an adequate number of bridge maintenance crews with proper skills…	…then we will not be able to complete needed maintenance and our conditions will deteriorate.	Likely	Moderate	High	ITD will continue to staff and fund its bridge maintenance crews to keep pace with maintenance needs.
R27	If we do not raise some of bridges with low vertical clearance…	..then bridge strikes will continue.	Likely	Minor	Medium	As projects address bridges, ITD will ensure that adequate vertical clearances are addressed.
R28	If we do not seismically retrofit our older structures…	…they will be vulnerable to seismic events.	Possible	Moderate	Medium	ITD will continue its seismic retrofit program to gradually address this need.

Figure 6-5: Risks Specific to Maintaining Structures in a State of Good Repair

	Objective	Ensure ITD Has the Skilled Staff to Adequately Maintain Our Assets.				
	Risk Event	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R29	If maintenance crews continue to be utilized for construction inspection…	…then we may not have enough crews for routine bridge and pavement maintenance.	Possible	Minor	Low	ITD will monitor mainteance needs and ensure that adequate hours are provided for maintenance functions.
R30	If we continue to have many speciality functions that are filled by only one person..	…then we may have continued inefficiencies and delays when those staff leave or are not available.	Likely	Minor	Medium	ITD will try to use cross training where possible to address this issue.
R31	If our staff does not develop the ability to use the new pavement management system….	…then we will not take full advantage of its capabilities.	Likely	Minor	Medium	As ITD improves its existing pavement management system or develops a new one, it will also provide training so staff can benefit from the full functionality of the system.
R32	If we do not institute a knowledge transfer and succession planning effort…	…then we will lose institutional knowledge as our experienced staff retires.	Likely	Minor	Medium	ITD will try to use cross training where possible to address this issue.

Figure 6-6: Risks to Having Skilled Staff to Sustain Assets

	Objective	To Provide the Data and Information ITD Needs to Sustain Its Bridge and Pavement Conditions.				
	Risk Event	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R33	If information technology services and data systems are not kept current with ITD needs…	…asset management decision making will be impeded leading to less-than-optimal decisions and investments.	Likely	Major	**High**	ITD will continue its comprehensive efforts to review the IT strategy, ensure executive support, improve GIS and locational functionality, implement data governance, manage information as an asset, and conduct an IT gap assesment.
R34	If we don't customize new software carefuly and with well-defined customer requirements..	…we could drive up the cost and lower the performance of any new application.	Likely	Moderate	High	ITD will carefully document customer requirements if new software is acquired and will ensure that cost, complexity, and functionality are balanced if the software is customized.
R35	If we don't develop a "single source of truth" for multiple data needs…	…then we will continue to get different answers from different data sets and frustrate users and stakeholders.	Very Likely	Moderate	High	ITD will continue its efforts to standardize its databases and ensure that to the extent possible data is recorded once and used accurately across many information platforms.
R36	If we don't capture the costs, locations, and effects of routine maintenance…	…then we will not have accurate information about asset performance, costs, or condition.	Very Likely	Minor	Medium	ITD will contiue efforts to accurately capture the costs and extent of maintenance activites to better understand asset performance.
R37	If we don't make data readily accessible…	… we will continue to frustrate our users and stakeholders.	Likely	Minor	Medium	ITD will continue its efforts to provide accurate, easy-to-access data for decision making.
R38	If legacy data that we still use is eliminated in an update process…	..then we will lack some data that remains important.	Likely	Insignificant	Low	As ITD updates its asset management and other systejms it will document the use of legacy data and ensure it remains accessible for those who need it.
R39	If Federal data-collection requirements are different than ours…	…then we will experience inefficiencies in data collection, storage, and access.	Very Likely	Minor	Medium	ITD will monitor Federal requirements and urge FHWA to not adopt onerous new reporting requirements.

Figure 6-7: Data and Information Risks to Sustaining Assets in a State of Good Repair

	Objective	Protect Our Assets and Citizens from External Threats.				
	Risk Event	**Risk Effect**	**Likelihood**	**Impact**	**Rating**	**Response**
R40	If we continue to experience periodic flooding…	…then we will have to respond to localized road closures and damage.	Likely	Minor	Medium	ITD will maintain its ability to respond to periodic flooding and reopen roads as quickly as possible.
R41	If we don't manage redundant routes that needed for emergencies…	…we may not have adequate capacity if major routes are closed by emergencies.	Unlikely	Moderate	Medium	ITD will remain cogizant of which routes provide redundant access during emergencies and keep them in a state of good repair.

Figure 6-8: Risks from External Threats That Could Affect Asset Conditions

Chapter 7 - Financial Planning Process

The Idaho Transportation Department (ITD) has a robust financial planning process to ensure that the state's bridges and highways are properly maintained. This document describes the process ITD employs to identify available revenue sources and to program funds for maintaining the state's transportation infrastructure assets. The process begins at the highest level with the identification of State, Federal, and Local resources available for the national highway system. The next step is to account for the expenditures necessary for department operations. The funding available for the Highway Funding Plan (HFP) is calculated by subtracting the department operating costs from the total available revenue.

The HFP includes all funds available for the maintenance, operations and construction of the bridges and highways under ITD's jurisdiction. There are many funding needs in the HFP in addition to the infrastructure in the asset management plan. Examples of these funding needs include those programmed for Transportation Alternatives, Recreational Trails, Railroad Crossings, and many local programs. These funds are subtracted from total available in the HFP to calculate the amount of funding available for the Transportation Asset Management Plan (TAMP). This section details the steps ITD employs to identify the funding for the TAMP.

Financial Plan Requirements

FHWA is quite specific about financial plans. It defines them as a long-term plan spanning 10 years or longer, presenting a State DOT's estimates of projected available financial resources and predicted expenditures in major asset categories that can be used to achieve State DOT targets for asset condition during the plan period, and highlighting how resources are expected to be allocated based on asset strategies, needs, shortfalls, and agency policies.

The financial plan leads to investment strategies. Those are defined as a set of strategies that result from evaluating various levels of funding to achieve State DOT targets for asset condition and system performance effectiveness at a minimum practicable cost while managing risks.

FHWA in Sec. 515.7 (6) (d) says the state shall establish a financial plan development process that identifies annual costs over a minimum of 10 years. The plan shall produce:

> (1) The estimated cost of expected future work to implement investment strategies contained in the asset management plan, by State fiscal year and work type;
>
> (2) The estimated funding levels that are expected to be reasonably available, by fiscal year, to address the costs of future work types. State DOTs may estimate the amount of available future funding using historical values where the future funding amount is uncertain;
>
> (3) Identification of anticipated funding sources; and
>
> (4) An estimate of the value of the agency's NHS pavement and bridge assets and the needed investment on an annual basis to maintain the value of these assets.

ITD Funding Sources

ITD's revenues come from many sources each of which are described below.

State Highway User Revenue

Approximately half of the revenue generated for the maintenance and operation of the infrastructure in ITD's jurisdiction is from state sources. This section includes a description of these sources.

Beginning Cash Balance

Known or projected operational cost savings and receipts above forecast can yield uncommitted cash balances at the end of each year. These cash balances are available in addition to forecasted revenue to support operational and program costs in subsequent year(s).

Highway Distribution Account (HDA)

The Highway Distribution Account includes state highway user revenue collected from motor fuels tax (gasoline and special fuels), motor vehicle registrations, and miscellaneous fees and permits. The SHA receives 57 percent of this revenue; the remaining amount is distributed to local highway jurisdictions and the Idaho State Police.

Ethanol Exemption

Seven percent of the motor fuel revenue is distributed to the State Highway account because of the elimination of the tax exemption for ethanol.

New User Revenue

During the 2015 Legislative session, the tax rate for motor fuels and registration fees for motor vehicles were raised. This additional revenue is reported independent of other revenue sources. Sixty percent of this revenue is directed to the SHA, the remainder is distributed to local highway jurisdictions.

State Highway Account (SHA) Miscellaneous Revenue

Certain registration, permit, and title fees identified in Idaho Code as well as miscellaneous receipts for sale of equipment, services, and supplies are also distributed to the SHA.

Estimates of state funds available for the HFP take into account projected revenues, the reservation of state matching funds for federal aid, and other operational needs not shown in the STIP.

The amount of state highway funding can be impacted by legislation passed in any given year. 2017 was an active year for the Idaho Legislature. The highlights include passage of House Bill 20 and removing the additional $75 fee for hybrid vehicles unless the vehicle is identified as a "plug-in" hybrid. House Bill 20 reduced annual transportation revenue to ITD by approximately $600,000.

Senate Bill 1043 allows agricultural vehicles to be moved without having to obtain an overlegal permit. This bill reduced annual transportation revenue by $54,000.

The estimated state funding for FY19 through FY25 available for highway capital construction averages above $200 million annually. This includes new highway user revenue and other funding generated by

bills passed during the 2017 legislative session.

GARVEE Bond Proceeds

GARVEE (Grant Anticipation Revenue Vehicle) bonds are revenue bonds that pledge the full faith and credit of the state. Idaho Code allows no more than thirty percent of ITD's federal apportionment to be used for GARVEE debt service. The department uses federal highway revenue to repay the bonds. Prior to FY17, the Idaho Legislature authorized the department to secure financing of $857 million of infrastructure improvements in the GARVEE program. Projects funded by those pre-FY17 authorizations were closed out during FY16.

The 2017 Idaho Legislature authorized the issuance of up to $300 million in GARVEE bonds. These bonds will be used to fund highway projects

The estimated debt service on $300 million in additional bonds is approximately $24.0 million annually. In combination with the $56.7 million in existing debt service, the total annual debt service, including $300 million of additional bonds, would be approximately $80.7 million ($74.5 million federal funds and $6.2 million state matching funds).

Cigarette Tax Revenue for Debt Service

The 2015 Legislature passed legislation directing Cigarette Tax revenue to pay approximately $4.7 million per year of the GARVEE debt service.

Strategic Initiative Program Fund (SIPF)

The 2015 Legislature directed ITD to establish and maintain a Strategic Initiatives Program and Fund. The purpose is to fund projects proposed by the department's six districts. The projects must compete for selection based on an analysis of their return on investment in prescribed categories.

In 2017, the Legislature passed Senate Bill 1206, which extended General Fund Surplus transfers by two years, directing them to the Strategic Initiatives Program fund and authorized a distribution of the fund with 60 percent to ITD and 40 percent to local highway jurisdictions administered by the Local Highway Technical Assistance Council (LHTAC).

The 2017 Legislature also passed House Bill 334, which added a category to the Strategic Initiatives Program Fund, relating to child pedestrian safety on the state and local systems.

The amount to be distributed after the end of FY17 is $27.7 million ($16.6 million to ITD and $11.1 million for local projects).

Transportation Expansion and Congestion Mitigation (TECM)

The 2017 Legislature also established the Transportation Expansion and Congestion Mitigation (TECM) Program and fund. The purpose of TECM is to fund projects that are chosen by the Idaho Transportation Board based on a project's ability to improve traffic flow and mitigate traffic times and congestion. The TECM fund receives revenue from one percent of sales tax after local revenue sharing, and all remaining moneys following the distribution of the cigarette tax revenue.

The forecasted TECM funding levels for FY19 through FY25 range from $16.9 million to $19.9 million annually.

Federal

As is the case with other state transportation departments, ITD relies heavily on federal funding to maintain its transportation infrastructure. These federal sources include:

- Excise taxes on gasoline and special fuels used to propel motor vehicles on public highways
- Weight-based taxes on heavy vehicles registered for interstate commerce
- Tax on the value of heavy commercial vehicle sales
- Weight-based excise tax on tires exceeding 40 pounds

This revenue is directed to Idaho through Federal transportation legislation, federal project-specific discretionary awards, or prior congressional earmark awards.

The current federal transportation authorization is the Fixing America's Surface Transportation Act (FAST). It establishes funding over federal fiscal years 2016 through 2020. The MAP-21 transportation program structure continues under the FAST Act with one substantial change, the inclusion of a new Freight program and a few minor changes.

Funding estimates for the federal highway program are $302.2 million in FY18, $309.0 million in FY19, and $316.4 million in FY20 through FY24. These estimates are listed in year-of-expenditure dollars. ITD assumes that obligation authority will be equal to 100 percent of estimated apportionments. Funding forecasts do not include year-end redistribution of obligational authority not used by other states.

Local

FHWA and the Idaho Transportation Board reserve certain federal funds for use by local public agencies. Local public agencies must pay the match on these federal funds most often at Idaho's sliding scale rate of 7.34 percent of the project cost. Local public agencies may also contribute funds in excess of the required match on federal projects or choose to contribute to state-funded projects. These are termed Local Participating funds. Finally, there may be some costs on a local project which the FHWA cannot reimburse based upon a certain rules or regulation. These funds do not participate in the established match arrangement so are termed Local Non-Participating costs.

Idaho Transportation Department Expenditures

Before ITD can dedicate funds to the Highway Funding Plan, it must dedicate a portion of the available funds to department operations.

Operations costs support programs outside those funded by the Highway Funding Plan, including Administration, Capital Facilities, Aeronautics, Motor Vehicles, and Highway Operations. This section describes the department's operating costs.

Department Operations

"Coming off the top" are expenditures for basic operations required to run the department, maintain roads, and provide people and equipment to manage the highway network.

Personnel

Costs for personnel who support Operations programs, including; full-time staff, temporary employees, overtime, shift-pay, and per diem for boards and commissions. These costs include employee salaries, employer benefit costs, and health insurance. Projections for annual increases in costs for salaries, benefits, and health insurance are reflected in the plan.

Operating Expenditures

Daily operating and seasonal costs are necessary to support delivery of Operations programs. Operating Expenditures cover a broad range of costs, including supplies, repair and maintenance, utilities, communications, fuel, road maintenance materials (asphalt, plant-mix), winter operations materials (salt, brine, and sand), insurance, etc. Operating expenditures reflect projected inflation and volume increases expected during the plan period.

Equipment

Acquisition cost of new and replacement equipment necessary for delivery of services in Operations programs. These costs include; road equipment, computers and network equipment; specific use, laboratory, and shop equipment.

Capital Facilities

Costs needed for maintaining, designing, and building department facilities.

Trustee and Benefits

Funds passed-through to entities authorized to carry out specialized program activities eligible for funding under provisions of the granting agency. This financial analysis does not carry any Trustee and Benefits resources used by the department's Operations programs.

Other Costs and Timing Adjustments Across Plan Years

Includes resources used for Operations not classified in the previous categories and addresses timing differences across plan years necessary to reconcile to available funding carried in each year of the current Highway Funding Plan.

Funding Available for Highway Program

The Program Targets spreadsheet begins with funding targets from the Highway Funding Plan. Specifically, it requires federal funds with match after takedown for indirect costs by year. It also requires state funds by appropriation by year. Idaho has a reduced sliding scale match rate for interstate work of 92.27 percent and for non-interstate work of 92.66 percent. The annual match rate for NHPP funds was obtained from the composite rate on programmed 2019 – 2025 projects.

Funds available to the State Highway System are placed into Performance Programs, which address rehabilitation and restoration of assets. Specifically, the TAMP is funded through the Pavement Preservation (Commerce), Restoration, Bridge Preservation, and Bridge Restoration Programs. Capacity projects sometimes have a reconstruction component to existing lanes which are also funds available to the TAMP.

Since we recently began our FY 2019 – 2026 Program Update, the annual targets for these programs were used in the TAMP. Each spring, the Transportation Board reviews pavement and bridge condition to determine funding targets for Pavements vs. Bridges vs. Safety & Capacity. The targets for the final two years of the TAMP flat lines the previous $80 million for Safety & Capacity, $80 million for bridges, and the remaining funds for pavement. Actual Safety & Capacity projects were used to estimate its contribution toward the TAMP.

Similarly, the projects programmed in FY 2019 – 2025 were used to estimate how much of these funds are used on the National Highway System, including interstate, as opposed to state highways. Annual ratios of NHS project costs vs. the whole were prepared and multiplied against the above targets to determine funding available to the TAMP on the National Highway System.

Funds not used for State Highway System State of Good Repair

The HFP includes many programs that are not intended to address the "state of good repair" on the state highway system. These programs are described in this section.

Highway / MPO Planning

The purpose of the Metropolitan Planning Program is to fund planning for Idaho's five metropolitan planning organizations in order to establish a cooperative, continuous, and comprehensive framework for making transportation investment decisions and to carry out transportation planning activities throughout the State.

Transportation Alternatives

The purpose of the Transportation Alternatives Program (TAP) is to provide funding for programs and projects defined as transportation alternatives, including on and off-road pedestrian and bicycle facilities, infrastructure projects for improving non-driver access to public transportation and enhanced mobility, community improvement activities, and environmental mitigation; recreational trail program projects; safe routes to school projects; and projects for the planning, design, or construction of boulevards and other roadways largely in the right-of-way of former Interstate System routes or other divided highways.

Recreational Trails

Apportionments are transferred to the Department of Parks and Recreation for their administration of the Recreational trails program projects.

Surface Transportation - Local Programs

The purpose of the STP-Local Urban Program is to ensure that local federal-aid routes within urban areas (population 5,000 to 200,000) are in good condition and unrestricted. Projects within this program should preserve and improve the conditions of the local federal-aid route as well as encourage and promote the safe and efficient management, operation, and development of the transportation systems to serve the

mobility needs of people and foster economic growth and development.

Local/Off system Bridge

The purpose of the Bridge Off-System Program ensures that local bridges off the federal aid system are in good condition and unrestricted.

Railroad Crossing

The purpose of the Rail-Highway Crossing Program is to enhance safety at Idaho's public railroad-highway crossings, provide/encourage rail safety education, and fulfill federal rail reporting requirements.

Local Safety

The purpose of the Local Highway Safety Improvement Program (LHSIP) is to work towards the elimination of fatal and serious injury crashes on the local roadway system in Idaho. The Local Highway Technical Assistance Council (LHTAC), through an application process, selects highway safety improvement projects for submission into the Program in each ITD District. The selected projects are reviewed, verified and justified for compliance with funding regulations prior to inclusion into the Local Highway Safety Improvement Program (HSIP) portion of the Idaho Transportation Investment Program (ITIP).

Local Participating

Local public agencies may contribute funds in excess of the required match on federal projects or choose to contribute to state-funded projects. These are termed Local Participating funds.

Local Non-Participating

There may be some costs on a local project which the FHWA cannot or will not reimburse based upon a certain rules or regulation. These funds do not participate in the established match arrangement so are termed Local Non-Participating funds.

Local Match

Local funds required as the match for Federal funds on a local project.

GARVEE (Expansion)

The 2017 Idaho Legislature authorized the issuance of up to $300 million in GARVEE bonds. These bonds will be used to fund highway projects

GARVEE Bond Debt Service *

The estimated debt service on $300 million in additional bonds is approximately $24.0 million annually. In combination with the $56.7 million in existing debt service, the total annual debt service, including $300 million of additional bonds, would be approximately $80.7 million ($74.5 million federal funds and $6.2 million state matching funds).

SIPF – Local

In 2017, the Legislature extended General Fund Surplus transfers by two years, directing them to the Strategic Initiatives Program fund and authorized a distribution of the fund with 60 percent to ITD and 40 percent to local highway jurisdictions administered by the Local Highway Technical Assistance Council

(LHTAC).

SIPF - Child Pedestrian Safety

The 2017 Legislature also added a category to the Strategic Initiatives Program Fund relating to child pedestrian safety on the state and local systems.

Funding Available for Transportation Asset Management

The funds remaining after addressing the department's operating needs and funding the programs not used for state highway system state of good repair are available for maintenance of the infrastructure included in the TAMP. This section describes the programs dedicated to these assets.

Pavement Preservation (Commerce)

The purpose of the Pavement Preservation Program is to employ a planned strategy of cost effective treatments to the surface of a structurally sound roadway that preserves the system, retards future deterioration, and maintains or improves the functional condition of the commerce route system without substantially increasing structural capacity. Within this funding category, the specific work type allowed is preservation.

Pavement Preservation (Non-Commerce)

The purpose of the Pavement Preservation Program is to employ a planned strategy of cost effective treatments that preserves the non-commerce system and retards future deterioration. Within this funding category, the specific work type allowed is preservation.

Pavement Restoration

The purpose of the Restoration Program is to fund pavement projects that are more extensive than pavement preventative maintenance. These structural enhancements are used to extend the service life of an existing pavement and/or improve its load carrying capacity or completely rebuild a pavement structure. Restoration of other assets and traffic operation projects are also placed in this program. Within this funding category all five work types (e.g., Maintenance, Initial Construction, Reconstruction, Rehabilitation, and Preservation) are allowed.

Bridge Preservation

The purpose of the Bridge Preservation Program is to ensure that Idaho's state highway system bridge assets are in good repair and unrestricted. Within this funding category, the specific work type allowed is preservation.

Bridge Restoration

The purpose of the Bridge Restoration Program is to ensure that Idaho's state highway system bridge assets are in good repair and unrestricted. Within this funding category all five work types (Initial Construction, Reconstruction, Rehabilitation, and Preservation) are allowed.

Safety & Capacity

The purpose of the Safety and Capacity (S&C) Program is to ensure that ITD's state highway system is

reliable and unrestricted, provides a means to invest in economic opportunities, and applies Idaho's Highway Safety Improvement Program (HSIP) to advance the objectives and goals of ITD's Strategic Plan. The Safety and Capacity program determines project prioritization to using funds from designated funding sources.

The following tables show the expected revenues and expected expenditures. They form the "sources and uses" component of the asset management financial plan. The first four tables show expected revenues, or the sources. The last three show the expenditures, or the uses.

Table 7-1 summarizes the expected state revenues and their sources for ITD from 2019-2028. As can be seen, the Highway Distribution Account, which contains state motor fuel taxes and fees, provides the largest source of ITD's state revenue. In addition, as can be seen, some state funds are dedicated for specific programs, such as Transportation Expansion and Congestion Mitigation, and are not available for asset management purposes. These funds shown in Table 7-2 are those, which are allocated to ITD. Other state funds are distributed directly to local governments for transportation purposes.

All figures represent millions of dollars.

Table 7-1: Forecasted State Revenue Sources

FY 2019 - 2028 Proposed ITD Ten Year Transportation Plan

Cigarette Tax Revenue for Debt Service[6]	4.7	4.7	4.7	4.7	4.7	3.6	3.3	3.1	2.9	2.7	39.1
Total State Highway Funding Sources	$484.6	$458.7	$431.9	$359.8	$362.3	$364.9	$367.6	$370.4	$373.3	$376.1	$3,949.7

Table 7-2 illustrates the Federal revenues and their sources expected for 2018-2027. As with the State funds, not all Federal revenues are available for asset management purposes. As can be seen, much of the Surface Transportation Block Grant (STBG) funds are intended for urban areas, or for rural programs. Also, some are set aside for specific purposes such as Transportation Alternatives that fund projects such as bike paths. CMAQ funds are congestion mitigation/air quality funds that only can be used for congestion relief or transit projects.

Table 7-2: Forecasted Federal Revenue Sources

Figure 7-3 includes the expected local funds for the 10-years of the plan. Local funds are provided as match to the Federal-aid funds used by local governments. These funds are seldom applied to ITD asset management projects. Usually, local match is provided only when a local government accesses Federal-aid funds for a local bridge, pavement, or capacity project off the state highway system.

At the bottom, Table 7-3 summarizes all of the expected revenues from State, Federal, and local sources. As can be seen at the far-right bottom row, a total of $7.3262 billion is expected to be available from all sources for the years 2019-2028.

Table 7-3: Forecasted Local Revenue Sources Plus Summary of All Sources

FY 2019 - 2028 Proposed ITD Ten Year Transportation Plan
ITD Funding & Use Summary ($ in Millions, rounded)

date: 08-13-19

Highway -Local	FY2019	FY2020	FY2021	FY2022	FY2023	FY2024	FY2025	FY2026	FY2027	FY2028	10 Yr Total

NOTES - Funding Sources

1. FY18 - FY23 values based on Aug. 1, 2017 Forecast. FY24 - FY27 based on a +1% growth rate
2. FY18 - FY23 values based on Aug. 1, 2017 Forecast. FY24 - FY27 held constant at FY23 value
3. 300 million in new GARVEE bonds to fund projects selected by the Idaho Transportation Board
4. The 2017 Legislature also established the Transportation Expansion and Congestion Mitigation (TECM) Program and fund to improve traffic flow and mitigate traffic times and congestion. The TECM fund receives revenue from one percent of sales tax after local revenue sharing, and all remaining moneys following the distribution of the cigarette tax revenue.

percent will be distributed to local projects administered by the Local Highway Technical Assistance Council (LHTAC). Value carried in this plan reflects ITD's sixty percent portion of Strategic Initiatives Program Fund monies, only.

6. FY18 - FY23 Based on DFM Forecast (12-29-17). FY24 - FY28 based on a -7% growth rate.

The following tables show expenditures. Table 7-4 shows operational costs that are expected to be incurred between 2019 and 2028. These funds "come off the top" before revenues are made available for asset management purposes. These represent the essential expenditures needed for basic functions such as paying salaries, operating snowplows, maintaining garages and rest areas, paying for highway lighting, and other core functions. Total operational costs equal an estimated $2.4810 billion for the 10 years.

Table 7-4: Department Operations Expenditures and Remaining Available Revenues

FY 2019 - 2028 Proposed ITD Ten Year Transportation Plan
ITD Funding & Use Summary ($ in Millions, rounded)

date: 08-13-19

Total Funding Sources	$913.0	$795.7	$763.6	$696.3	$684.1	$689.0	$691.9	$694.7	$697.5	$700.4	$ 7,326.2

Department Operations	FY2019	FY2020	FY2021	FY2022	FY2023	FY2024	FY2025	FY2026	FY2027	FY2028	10 Year Total

Trustee and Benefits	--	--	--	--	--	--	--	--	--	--	-
Other Costs and Timing Adjustments Across Plan Years [2]	99.4	10.0	2.2	-5.3	-4.8	-5.5	-6.3	-5.7	-5.9	-9.7	68.5
Total Department Operations	$305.6	$237.1	$233.7	$230.9	$233.1	$237.6	$242.2	$248.7	$254.7	$257.5	$2,481.0

NOTES - Department Operations

1. Personnel costs for Operations programs, only. Personnel costs related to infrastructure assets are carried in Funding Available for Program. Adjusted for anticipated cost increases in employee salaries,
2. Costs not classified in other Operations categories and adjustments across plan years to reconcile available funding carried in each year of the current Highway Funding Plan.

When the $2.4810 billion in operating costs are subtracted from the $7.3262 billion in expected revenue, then $4.8452 remain for the highway program. Of the $5.3387, $4.4330 is available for basic highway purposes. To that is added about $460 million in funds for specific purposes. That includes $45.0 million in local funds to match projects and $300 million in the GARVEE bonds the legislature directs to capacity projects. In addition, $117.5 million is provided for preliminary engineering, which generally is project design, and construction engineering, which involves oversight and inspection of projects during construction.

Table 7-5: Funding Available after Operation Costs are Deducted

Table 7-7 shows the remaining $3.5244 billion is expected to be allocated for asset management and safety and capacity programs between FY2019 – FY2028.. As noted earlier in this report, ITD divides its highways into Commerce and Non-Commerce routes for prioritization. Generally, Commerce routes carry more than 300 trucks per day and represent the routes most important to the movement of people and goods in Idaho. The Commerce routes are maintained to a higher standard, although ITD keeps the Non-Commerce routes in adequate condition to fulfill their important function of providing access to all areas of the state. In addition, FHWA requires ITD to report on the conditions and expenditures on the National Highway System. The NHS represents the interstates and major routes across the country. There is considerable overlap between the Commerce routes and the NHS. As see in Table 7-6, an estimated $ 0.6766 billion is expected to be spent on basic pavement and bridge programs on the Non-NHS system between 2019 and 2028. That represents about 19 percent of the funds available after other programs are paid for as shown in the earlier tables. The remaining 81 percent, or $ 2.847 billion is allocated for National Highway System bridges, pavements, and safety and capacity projects.

Bridge Preservation and Supporting Infrastructure Assets derived from history

Based on the information in Table 7-6 ITD distributes 34 percent of the transportation budget toward pavements, 25 percent on bridges, and the balance on other asset management programs. Of the 1.228 billion allocated for pavement, 72 percent is dedicated to NHS pavements. Within NHS pavements with 16 percent of the funding being for preservation and 84 percent is directed toward restoration. Bridge funding is allocated between NHS bridge preservation (19 percent) and NHS bridge restoration (81 percent). This is consistent with the bridge investment strategy discussed in Chapter 8.

The ITD STIP shows very broad classification categories for treatment types (i.e. Pavement Preservation and Pavement Restoration). Within these broad classification numerous work types are available to be programed. Within the ITD accounting system, individual projects are tagged as to what work type they represent. Table 7-9 presents the ITD programed projects by work type over the next 10-years.

Bridge Preservation and Supporting Infrastructure Assets derived from history

Initial Pavement Construction includes major widening (reconstruction confounded), turnbays, and new routes (confounds bridge initial construction)

Table 7-8 provides a high-level summary of all the preceding tables. Out of $7.215 billion, 32 percent goes to operations, $23 percent to non-asset management programs such as highway safety or local programs, 22 percent goes to maintaining the lower-volume routes off of the National Highway System, 4 percent is estimated to go for new capacity or safety programs, and 19 percent is expected to be available to maintain the bridges, pavements and related assets on the National Highway System.

Table 7-10: Summary of Revenue and Expenditures

Total Revenue and Allocations (Billions)		Percent of Total
Total Revenue	$7.3262	
Operations, Personnel, Equipment	-2.481	34%
Safety, Local, and Other Non-Asset Management Purposes	-$1.321	18%
Asset Management Purposes	-3.524	48%

Asset Valuation

Asset valuation is the assignment of monetary value to physical assets based upon their condition, cost to construct, age, obsolescence and other factors. The rationale for reporting asset valuation is to ensure that investments are adequate to ensure that the public's investment in its highway network is maintained. Highway networks generally represent a state's largest capital investment. Investing adequately in them can ensure that future generations inherit a well-maintained system, and not a major liability that is in a state of disrepair and requires substantial investment to maintain.

ITD estimated the value of its assets for this asset management plan using the concept of Depreciated Replacement Cost. This is an accounting concept adopted in Australia and Great Britain. It seeks to estimate the value of highway assets "as is." That is, what would it cost to replace them "in kind" to their current conditions?

This depreciation method differs from the historic cost method often used to estimate asset values. Historic cost usually applies a fixed amount of deterioration to an asset based entirely on its age. For example, if a bridge is built for $1 million and is expected to provide a useful life of 50 years, its value is depreciated by two percent annually. At the end of 50 years, the bridge will have a "book value" of $0. Even if the bridge has been rehabilitated and is in good condition, it still will be carried on the books at a value of $0. By this logic, the Golden Gate Bridge and Brooklyn Bridge have no monetary value simply because of their age.

The historic cost method provides little value for asset management. If an asset is valued at $0 there is

little incentive to invest further in its maintenance. However, as a practical matter, an aged bridge or pavement could have significant utility and warrant substantial maintenance and investment to prolong its useful life.

Bridge Asset Valuation

To calculate the depreciated replacement cost of ITD bridges, the analysis first estimates what it would cost to replace all of the ITD bridges. This provides an "as new" or "replacement cost" estimate of the ITD bridge assets. Using Federal Highway data on bridge size, age, condition, and cost per square foot to replace, the following values are estimated.

Table 7-11: Estimated Depreciated Replacement Cost for ITD NHS Bridges.

Depreciated Replacement Cost Exercise for Structures							
System	Total Sq.Ft.	Cost Per Sq.Ft.*	Cost to Replace All	Average Condition	As New Condition	Discounted by Condition	Depreciated Replacement Cost
Interstate	3,560,569	$132	$469,995,108	6.4	9	71%	$333,696,527
NHS	4,714,103	$182	$857,966,746	6.4	9	71%	$609,156,390
Total	$7,826,332		$1,327,961,854				$942,852,917
**FHWA Table HM-48*							

The logic of the analysis follows.

I. FHWA bridge data indicate that ITD owns 7.8 million square feet of NHS bridges and 4.3 million square feet of Non-NHS structures.
II. The cost to replace NHS bridges based on 2016 ITD data submitted to FHWA is $132 per square foot and $182 per square foot for Non-NHS structures.
III. Multiplying the square foot area by the cost to replace generates a total Replacement Cost of $1.818 billion to replace all of Idaho's bridges.
IV. Bridges are rated from 0-9 with 9 representing an "as new" structure.
V. The average condition of all ITD bridges is 6.4 out of the 0-9 scale.
VI. Dividing 6.4 by 9 equals 71 percent. In other words, ITD's bridges are in 71 percent of "as new" condition.
VII. Depreciating the Replacement Cost by the 71 percent, which represents their current condition, generates a Depreciated Replacement Value of $942,852,917.

ITD plans to invest about $80 million annually in bridge capital projects that include preservation, rehabilitation, and replacement. Additionally, each of the six ITD districts conducts in-house bridge maintenance, and some contract maintenance. The capital investment of $80 million represents 6.2 percent of the Depreciated Replacement Cost invested in the bridge inventory annually. ITD estimates this level of investment will be adequate to sustain current bridge investments for the next decade. It bases this estimate on past trends, which indicate that this level has been adequate to sustain conditions. In addition,

when projected over 10 years, $800 million will be invested in bridges, which represents 61 percent of the Depreciated Replacement Cost. Considering the relatively long-life of structures and slow annual deterioration, this investment appears adequate to sustain asset values for the next decade. However, beyond 10 years, more of the department's large structure will surpass their fortieth year. A "wave" or "bubble" of higher bridge investment needs will occur over the next 20 years. These structures are likely to have a higher per square foot cost than the typical Idaho structure. ITD will begin planning for a long-term strategy to ensure that bridge conditions and asset values can be preserved in the decade following this asset management plan.

Additionally, the per square foot cost show in Table 7-11 does not include some "soft" costs of design, maintenance of traffic, or right of way. Some states estimate that an additional 25 percent is needed in addition to the base square foot costs. Therefore, estimate investment levels should consider these "soft cost" needs.

NHS Pavement Asset Valuation

A similar logic was used to calculate a depreciated asset valuation for NHS pavements. This calculation is very conservative and does not include costs for right-of-way, lighting, safety elements or other costs such as design or inspection. It uses only a cost-per-lane mile estimate for pavement and multiplies it by lane miles.

Table 7-12: Depreciated Replacement Costs for ITD NHS Pavements

Depreciated Replacement Cost Exercise for NHS Pavements					
System	Lane Miles	Cost to Replace Per Lane Mile	Pavement Replacement Cost	Percent Not Poor	Depreciated Replacement Cost
Interstate	2530	$1,200,000	$3,036000,000	99.50%	$3,020,820,000
NHS	5,009	$625,000	$3,130,625,000	99.64%	$3,119,354,750
Total	**7,608**		**$6,166,625,000**		**$6,140,174,750**

FHWA data indicate that Idaho has 2,530 lanes miles of Interstates and 5,009 lane miles of non-Interstate NHS for 7,608 lane miles. ITD has generated a planning level estimate combining unit costs for urban and rural Interstate highways of $1,200,000 per lane mile for pavement replacement. For NHS routes used a planning level cost of $625,000. As can be seen when the unit costs for pavement replacement are multiplied by the lane miles it generates a replacement cost of $6,166,625,000 for the replacement cost of NHS pavements. Current conditions indicate that about 99.5 percent of Interstate pavements meet FHWA target and 99.64 percent of NHS pavements meet FHWA target. Using those values to discount conditions, an estimated depreciated replacement cost of $6,140,174,750 is calculated.

ITD estimates that its current investments will be adequate to sustain these asset values. This assumption is based upon the pavement modeling that indicates current investments will result in the department

continuing to meet its pavement condition goals.

Chapter 8 - Investment Strategies

ITD deploys a systematic process to develop and annually update its investment strategies.

ITD publishes the Idaho Transportation Investment Program (ITIP), which is like a STIP. Until recently it included a five-year estimate of revenues by revenue source and a detailed list of annual expenditures by program category. It also included a detailed projects list and a narrative explaining changes in program priorities based upon factors such as changing highway crash rates or changing asset conditions. In April of 2017, the ITD board extended the ITIP to a seven-year program.

The ITIP in many ways resembles the asset management financial plan that FHWA requires except that it addresses seven years and not 10. The common elements for both include:

- A multi-year estimate of revenues by revenue source;
- A year-by-year allocation of funds by program;
- A description of the board's rationale for changing allocations caused by changing asset conditions or crash rates;
- Although risks and gaps are not described in those terms, the ITD narrative explains how ITD and its board allocate funds to meet the transportation needs of the state. The narrative describes the funding sources, the restrictions on each source, and how allocations of the available resources are made to optimize the state's transportation performance. Table 8-1 includes the month-by-month processes that lead to approval of the ITIP and the agency's STIP.

Investment Strategy Requirements

FHWA requires the asset management plan to include investment strategies, which it defines as a set of strategies that result from evaluating various levels of funding to achieve State DOT targets for asset condition and system performance effectiveness at a minimum practicable cost while managing risks.

Regulations also say that states must have an investment strategy process that describes how investment strategies are influenced by:

(1) Performance gap analysis

(2) Life-cycle planning for asset classes or asset sub-groups

(3) Risk management analysis; and

(4) Anticipated available funding and estimated cost of expected future work types associated with various candidate strategies based on the financial plan.

An asset management plan shall discuss how the plan's investment strategies collectively would make or support progress toward:

(1) Achieving and sustaining a desired state of good repair over the life cycle of the assets

(2) Improving or preserving the condition of the assets and the performance of the NHS relating to physical assets

(3) Achieving the State DOT targets for asset condition and performance of the NHS, and

(4) Achieving the national goals for safety, relief of congestion, movement of freight and preservation or asset conditions.

Table 8-1: The ITIP Development Cycle

ITIP Development Calendar	
January	ITD publishes estimates of available funding, program descriptions, program targets, and a call for projects to MPOs, the LHTAC, and ITD's six districts. Districts are provided in advance with ITD's pavement-condition data and pavement management system analysis of their district conditions and recommended treatments and investment levels. District Offices also continually collaborate with the headquarters bridge staff to assess bridge conditions and identify needed bridge treatments.
March/May	The Idaho Transportation Board reviews condition targets, progress from the past year, reviews the agency's performance dashboard and receives project requests. It then develops a draft ITIP.
June	The transportation board reviews the draft ITIP and approves releasing it for public review and comment.
July	The draft ITIP is provided for public review and comment.
August	ITD staff develops a draft final ITIP incorporating the public comments.
September	ITD submits its recommended ITIP to the board.
November	The board approves submitting the State Transportation Improvement Program (STIP) to FHWA for approval, and the STIP incorporates the first four years of the ITIP.
December	FHWA and the Federal Transit Administration approve the STIP.
Ongoing	The ITD obtains input from citizens, elected officials, tribal governments, state and Federal agencies, MPOs, the LHTAC, and other interested parties.

ITD's investment strategy process satisfies the Federal requirements, although the ITIP process predates the Federal requirements by many years. This section will examine each Federal requirement and how it is addressed.

Performance Gap Analysis

ITD staff and the Idaho Transportation Board review gaps in performance annually as part of the process for developing the ITIP, which includes the investment strategies. ITD regularly updates it performance dashboard and the transportation board reviews the results. The performance reports include reviews of trends such as bridge and pavement conditions and crash rates.

The review also includes consideration of sub-network changes such as changes in conditions on the Commerce Routes versus the Non-Commerce Routes, and changes in the six districts. The adoption of the Commerce and Non-Commerce division in 2015 was driven by ITD's need to prioritize its scarce resources on the most highly travelled routes and make an investment tradeoff to avoid a gap in Commerce Route conditions. The Commerce Routes are those that have more than 300-trucks per day and move the most people and freight. Through prioritization, ITD made a risk-based decision to prevent a gap in system conditions from developing on the major routes. At the time the Commerce/Non-Commerce prioritization was made, the change was not driven by a response to the MAP-21 requirements to sustain conditions on the NHS. However, because the Commerce Routes include the NHS, the effect was to prioritize the NHS for investment.

One investment strategy is to prioritize the Commerce Routes and maintain them with more robust treatments while applying only thin treatments and conducting maintenance activities on the lower-volume Non-Commerce routes. For the commerce routes, 85 percent overall are in good or fair condition, which is above the target of 80 percent. For non-commerce routes, 84.2 percent are good or fair, which is just below target. ITD further stratifies its pavement investments by how it measures pavement performance. Pavements are ranked by three criteria, cracking, International Roughness Index (IRI), and rutting. The three distresses are measured and all pavements scored on a composite scale (0 to 5). ITD requires a higher condition on Interstates and arterials to be rated as "good". Lower conditions on collectors can still be considered "good."

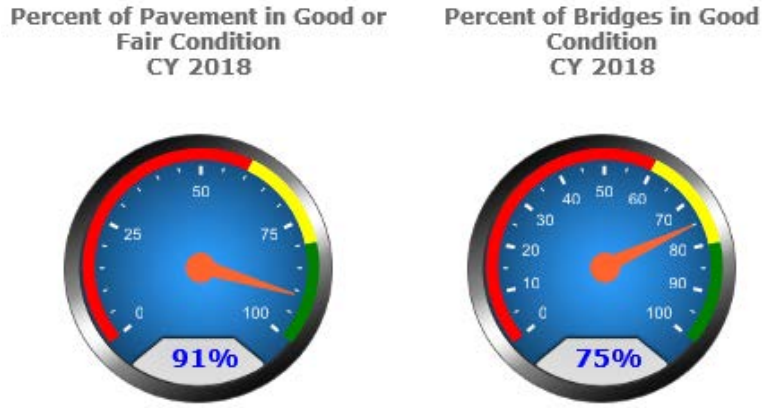

Figure 8-1: Screenshot of the Bridge and Pavement Condition Measures on the ITD Performance Dashboard

As reported in the Chapter 2, ITD's National Highway System and Interstate Highway System conditions are much better than the Federal minimums. Table 4-2, on page 4-2, summarizes the conditions compared to the federally allowable minimum levels. While the Federal maximum amount of poor Interstate pavement allowed is five percent, ITD has only 1.21 percent poor, and only 2.15 percent of the NHS is poor. Only 2.58 percent of NHS bridge deck area is poor compared to the allowable maximum of 10 percent.

The result of ITD's investment strategy to prioritize treatments on the Commerce Routes has been to ensure that higher volumes routes such as those on the Interstates and NHS are maintained in a state of good repair and in much better condition than Federal minimums. This strategy has prevented any gap in Interstate conditions from occurring and will be instrumental in closing the small gap, which exist on the NHS.

Life-Cycle Planning Influence

ITD's allocation of funds to bridge and pavements are also influenced by life-cycle planning analysis. Chapter 5 described in detail ITD's pavement management model. The model is run annually with updated pavement condition data. Model runs produce recommended statewide and district-by-district pavement programs based upon a mix of treatments to extend the life of pavements. The amounts needed to sustain pavements are the basis for the ITD staff's recommended pavement program funding levels that are presented to the Transportation Board.

Once funds are allocated to the districts, the districts develop their pavement programs. They base their program upon both the pavement model recommendations as well as their field observations and the need to coordinate the timing of projects with other projects on their local networks. The pavement management staff re-run the pavement model based upon the districts' projects to ensure that the program selected by the districts will meet the department's pavement targets.

Bridges are selected based upon the engineering analysis of the headquarters and the districts who jointly develop a projects list. The bridge program includes a balanced mix of bridge replacement, rehabilitation, preservation, and maintenance based upon lifecycle principles. ITD extends the life of its structures as far as economically feasible through this mix of treatments.

Life-cycle considerations are also seen in the program allocations. Specific line items are included in the ITIP to fund both pavement and bridge pavement preservation as well as bridge and pavement restoration. These funding splits provide the districts revenues specifically dedicated to preservation, which they can use to extend the life of pavements and bridges. Additionally, district maintenance crews perform regular bridge and pavement maintenance, which also extends the life of the assets.

Risk Analysis

ITD strategies are also driven by the need to reduce threats to asset conditions and the performance of the highway system. The highest ranked risks in the risk register are reflected in the investments and strategies undertaken by the department. For example, one of the highest ranked risks is that if programming decisions are dictated by the Idaho Legislature and do not reflect asset management priorities than the department may not be able to sustain adequate asset investment levels. To respond to this risk, ITD identified the need to urge legislators to continuing giving high priority to ITD's recommended investment levels for bridges and pavements.

Another highly ranked risk-mitigation strategy is to continue investing in bridge maintenance crews to ensure adequate maintenance of structures. An opportunity is the potential benefits if the department further improves its pavement management system, which it intends to do.

Several of the risks to asset conditions that were identified were ranked as low because the department is committed to asset management. For example, the risk of ITD de-emphasizing asset management was rated as low because of the widespread commitment to asset management in the department.

One long-term risk that was identified and which will be addressed is the need to develop a long-term plan for managing the department's largest structures. Although these structures generally are in good condition now, they are aging and will require significant investment over the next two decades. To respond to the risk of declining conditions among the largest structures, ITD will develop a multi-decade

plan for rehabilitating or replacing its largest structures.

The previously mentioned Commerce/Non-Commerce route bifurcation also is a risk-response strategy. It was adopted specifically to reduce the risk of declining asset conditions on the highest-volume routes. It also represents a higher risk tolerance for lower conditions on the lower volume Non-Commerce routes.

Funding Allocations Overall Tradeoff Analysis Strategy

Over the years, there have been many forces guiding how ITD would allocate funding between bridge, pavement, and other initiatives. In recent years, this question has receive more analytical attention. ITD's method of tradeoff analysis starts with modeling each of bridges and pavements at the system level. Using the individual asset management systems multiple scenarios are run, each one representing a given funding level. The scenarios are set up to maximize system benefit at minimum cost. This analysis results in the creation of an optimal portfolio of projects for each funding scenario considered. ITD then captures the system condition, e.g. percent of pavement in adequate condition, associated with a modeled year and funding level. With these data points, ITD creates a two variable regression (linear model) equation that allows us to interpolate more precise funding levels.

The modeled consequences of various funding levels is illustrated below for pavements between 2021 and 2026. The y-axis is funding level for pavements in millions of dollars. The resulting contours represent the system condition state for a given year/funding level).

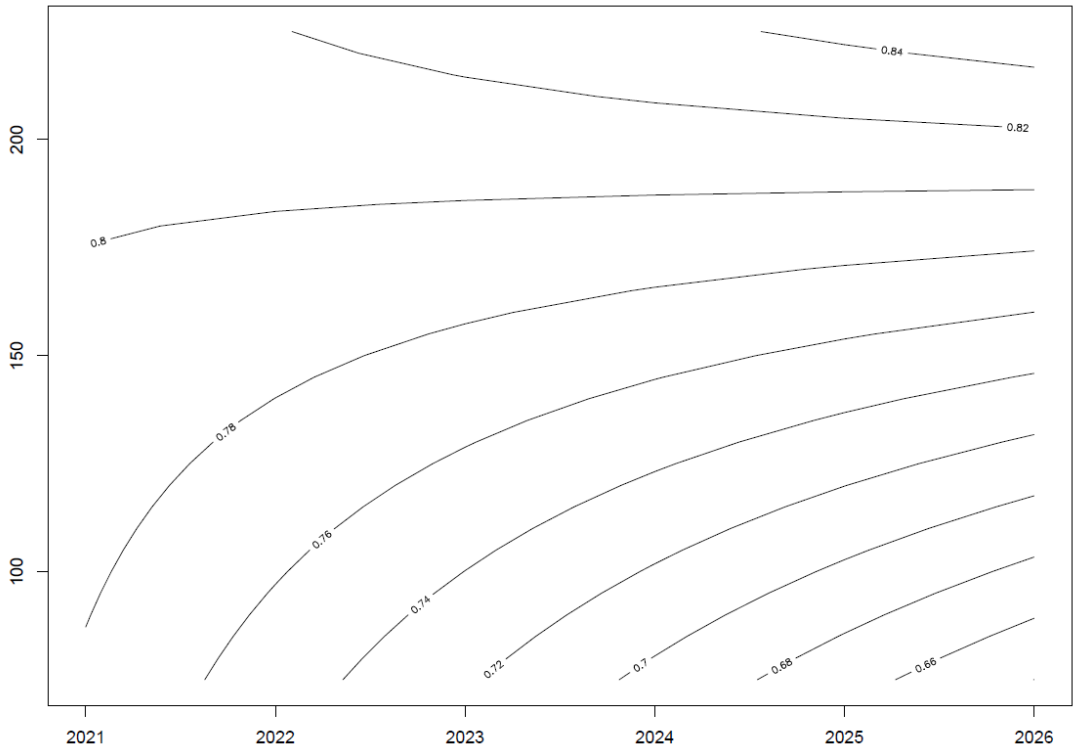

Figure 8-2: Performance Contours versus Funding Levels

Reassessment of target performance levels occurs every few years. In 2019, ITD targets having 80% good pavements and 80% good bridges in the outer years. According to this example contour chart provided, we would need to maintain an annual funding level of about $180 million to arrive at 2026 with 80% good pavements. A similar chart is created for bridges. Putting the two together, a total desired funding level for pavement and bridges is obtained.

As is often the case, the desired funding level is larger than the funding level modeled to meet our target system condition states. In that case, projects are considered individually and removed from both the bridges and pavement programs until a balanced solution can be reached.

In January of 2019, ITD was selected as the first state to test the next generation performance measures developed by FHWA project "*Development of Next Generation Pavement Performance Measures and Asset Management Methodologies to Support MAP-21 Performance Management Objectives".* This effort will assess the utility of several new performance metrics. These include the following:

Life-Cycle Measures:

- Remaining Service Interval (RSI)
- Annualized Cost Per Lane-Mile (ACLM)
- Cost Accrual Ratio (CAR)

Financial Measures:

- Asset Sustainability Index (ASI)
- Asset Sustainability Ratio (ASR)
- Asset Consumption Ratio (ACR)
- Backlog Reduction Ratio (BRR)

These performance measures will provide an additional means for ITD to assess the effectiveness of budget allocations with respect to performance enhancement. As part of this work, a computer program will be developed which would allow ITD to:

- easily forecast outcomes compared to funding targets;
- develop a spending plan with intermediate performance targets;
- graphically compare all fiscal scenarios considered;
- greatly enhance ITD's ability to perform funding trade-off analysis.

The following investment strategies for both pavements and bridge are noted because they result from evaluating various levels of funding to achieve State DOT targets for asset condition and system performance effectiveness at a minimum practicable cost while managing risks.

Pavement Investments

ITD retains as an investment strategy the prioritization of routes for pavement investment that are on the Commerce system and have average annual daily truck traffic in excess of 300-trucks per day. This risk-based strategy reflects the tradeoff ITD must make to balance its limited resources while also ensuring that conditions are maintained on the routes most important for freight movement, congestion relief,

safety, and the preservation of the state's most expensive highway assets. Associated with this investment strategy is a pavement allocation of $829.4 million for the NHS between 2018 and 2027. This includes $155.5 million for pavement preservation on the NHS and $673.9 million for pavement restoration. These amounts are based upon ITD's projections of investment levels necessary to sustain its NHS and Interstate Highway System pavement condition targets based on life-cycle cost strategies.

For Non-NHS routes, ITD estimates it will allocate a total of $1.5513 billion between 2018 and 2027 for both pavement and bridge projects. The pavement program assumes that districts will apply only light treatments to the Non-Commerce Route pavements to conserve resources to sustain the Commerce routes.

Significantly modified in 2019, the ITD TAMS is better able to monitor performance and forecasting 1/10-mile segment, per FHWA requirements. Additionally, these forecasts provide investments required by work type. The following is a description of the forecasting process.

1. The analysis is a two-step process:
    a. Step 1 – Run Multi-Constraint Optimization Analysis of budgets using Normal Management Sections (ITD typical project lengths)
    b. Step 2 – Run Estimate Master Work Program (MWP) Influence Analysis and apply the project results from step 1 against the 1/10th Mile Map-21 Analysis Sections to generate NHS results.
2. Apply 2019 and 2020 MWP results from the 2019 Work Program MWP to the Step 1 analysis.
    a. Year 1 (2019) of each scenario budget only covered the projects with no additional funds given (approx. $37.5 million)
    b. Year 2 (2020) of each scenario budget only covered the projects with no additional funds given (approx. $103 million)
3. Apply the results of Step 1 to Step 2 as a new MWP called "MWP-MAP21" in each budget scenario.
4. Apply three separate scenario budgets, with these budgets being applied in years 3-10 (beyond the programmed work of 2019 and 2020):
    a. $100 million/year for 10 years (-25%)
    b. $130 million/year for 10 years (typical)
    c. $160 million/year for 10 years (+25%)
5. Step 4 allows ITD to generate the Good/Fair/Poor statistics from these analyses and to report them out using a report built in TAMS.

NHS Pavement Investment and Performance Forecast

The output of this process facilitates ITD assessing NHS performance across various investment levels. To be clear, the investment level is forecasted across the entire SHS and the results are then extracted for each sub-network. Figure 8-3, shows the forecasted "good" performance of the interstate for ITD investment levels of $100/$130/$160 million across the network for the next ten years. As shown, investment of $100 million in the SHS is not adequate to sustain the performance of the interstate. For $130 million funding level, the forecast shows that in years 2023 and 2024 interstate performance falls slightly below the ITD specified target of 50 percent good pavement. However, in the following years performance picks up and exceeds the target. The $160 million scenario predicts that interstate performance will stay above

the ITD performance target though out the forecast period. Beginning on page 8-9, Figure 8-5 through Figure 8-7, show both "good" and "poor" performance on the individual forecast scenarios. Regardless of the funding level, it is forecasted that ITD interstate performance will stay well below the 4 percent threshold for percent poor interstate pavement. ITD selects the $130-million per year as its investment strategy.

Figure 8-4 shows the NHS Non-interstate performance for the same investment levels. It is interesting to note that in years 2023 and 2024 performance of "good" pavement falls off regardless of funding level. Further research is required. This appears to be related to a large portion of the NHS requiring resurfacing in these years. Additionally, it is noted that an investment in pavements of $160 million is forecast to be needed to obtain our performance target, 50% "good' pavement, by 2027. All other funding levels produce a positive increase in performance after 2024 but recovery to the performance goal is lengthened. Similar to the interstate pavements, regardless of the funding level, it is forecasted that ITD will remain well below the "poor" pavement performance threshold of eight percent.

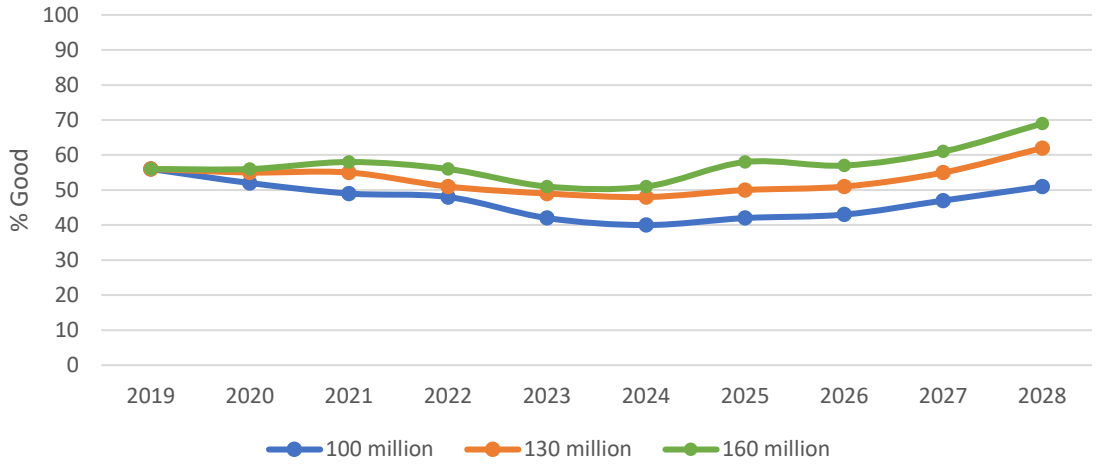

Figure 8-3: Forecasted Interstate Good Pavement Percentage vs Investment Level

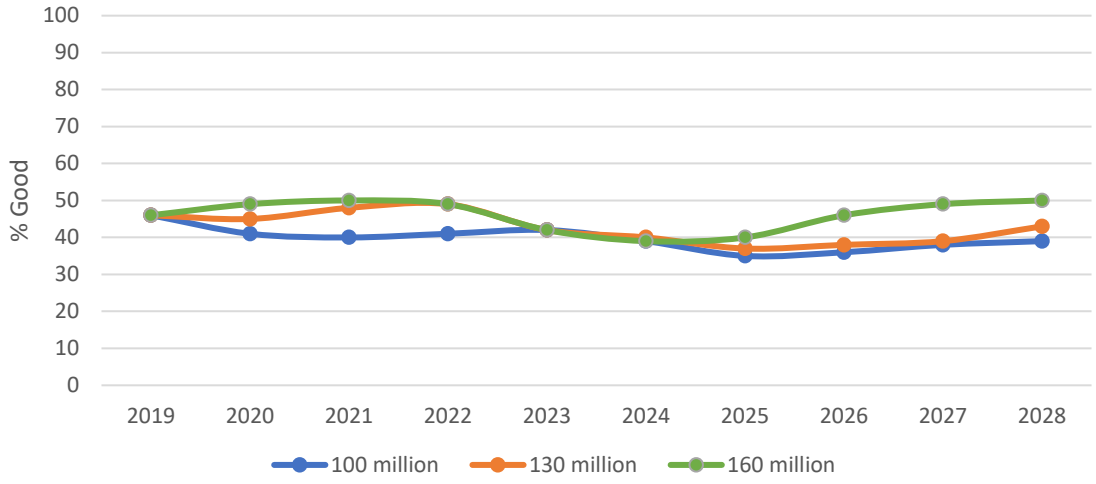

Figure 8-4: Forecasted NHS - Non-Interstate Good Pavement Percentage vs Investment Level

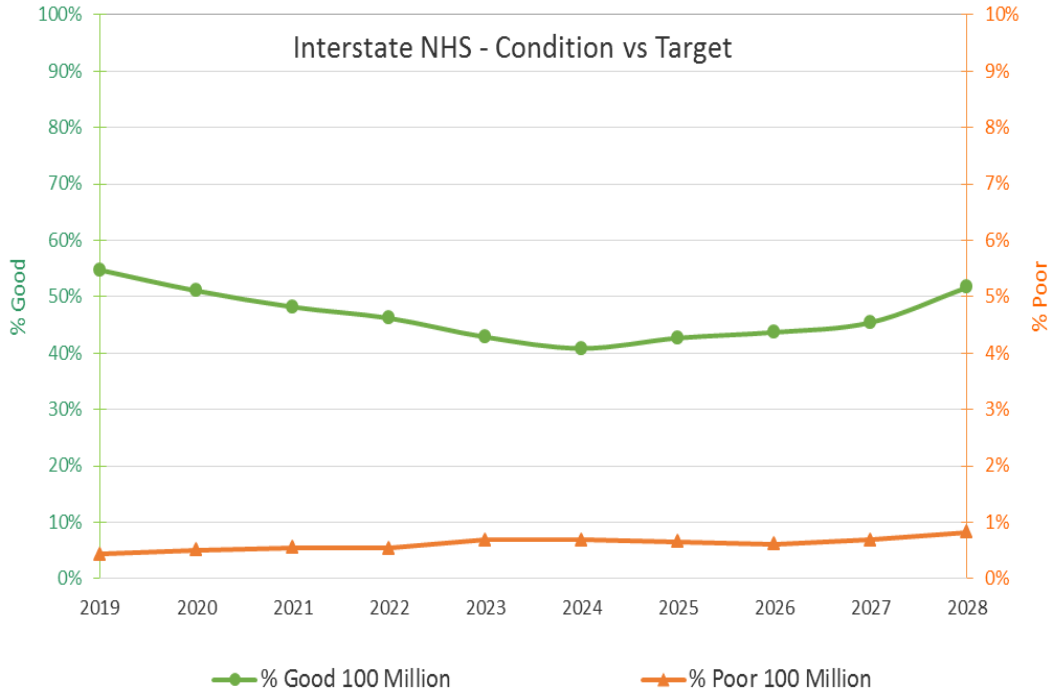

Figure 8-5: Interstate Condition 10-year Forecast with $100-million Budget

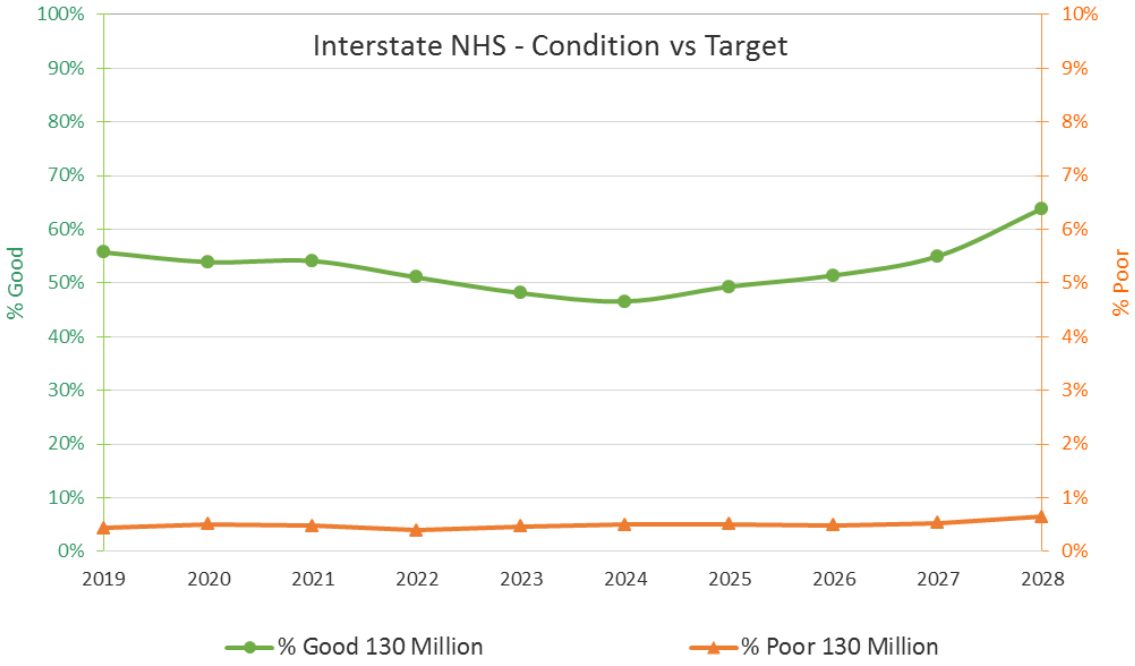

Figure 8-6: Interstate Condition 10-year Forecast with $130-million Budget

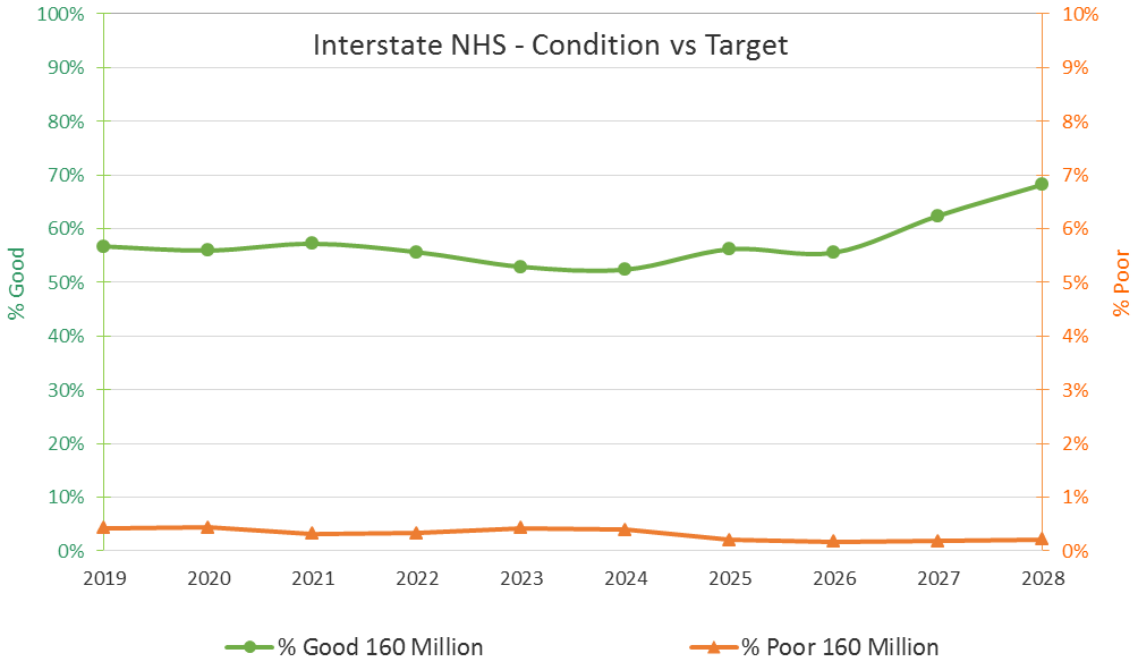

Figure 8-7: Interstate Condition 10-year Forecast with $160-million Budget

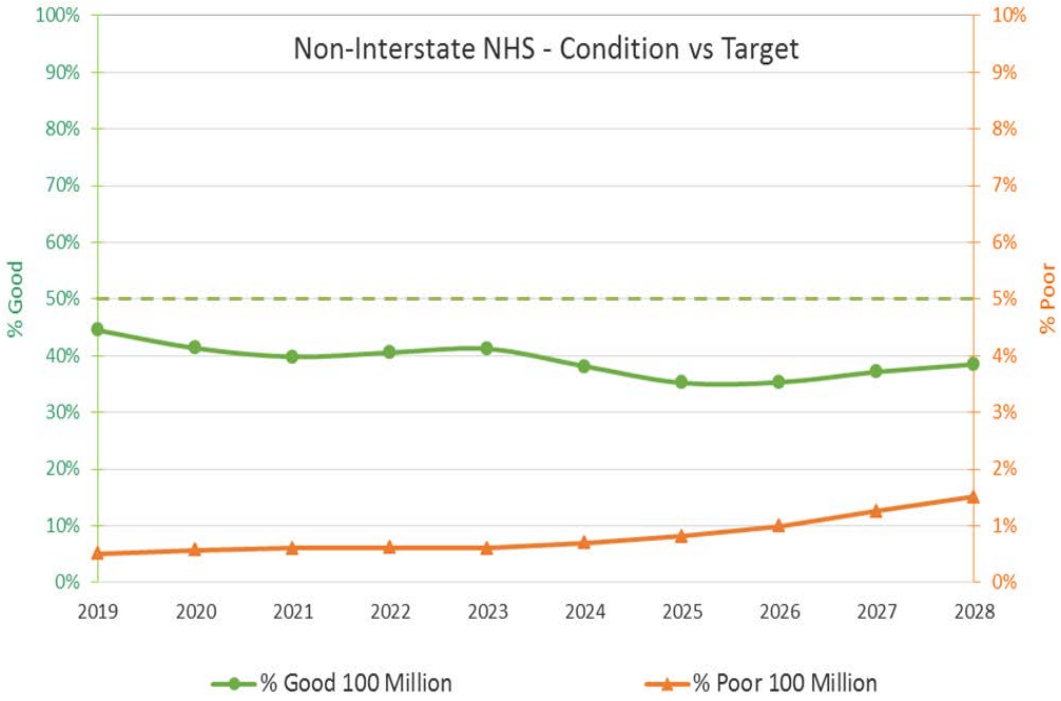

Figure 8-8: Non-Interstate NHS Condition 10-year Forecast with $100-million Budget

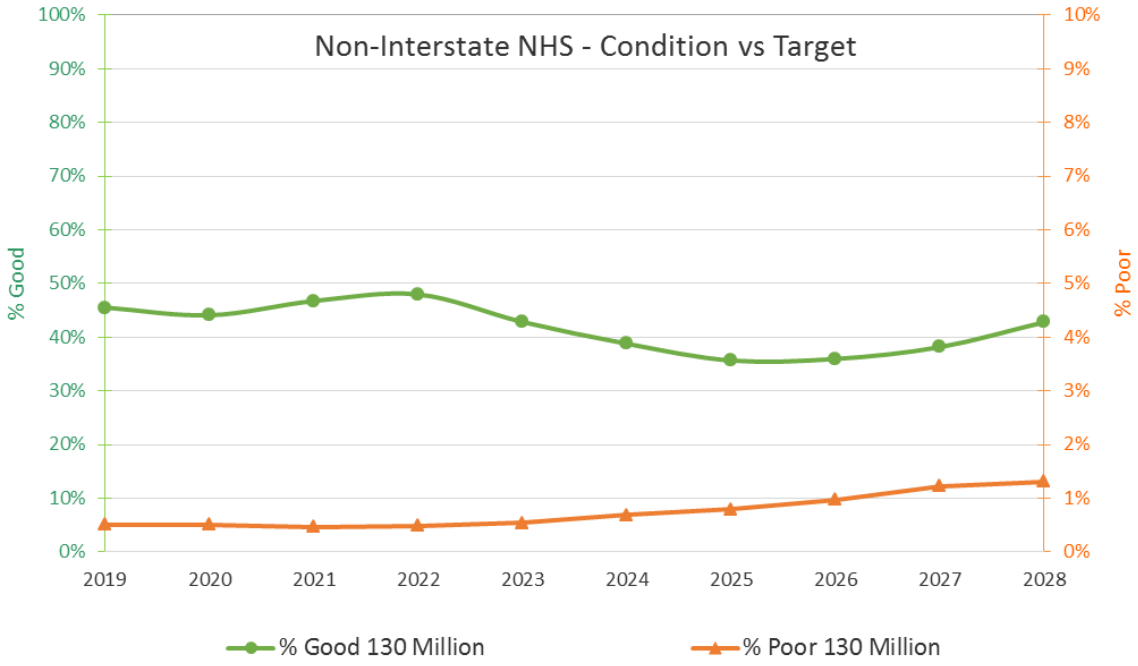

Figure 8-9: Non-Interstate NHS Condition 10-year Forecast with $130-million Budget

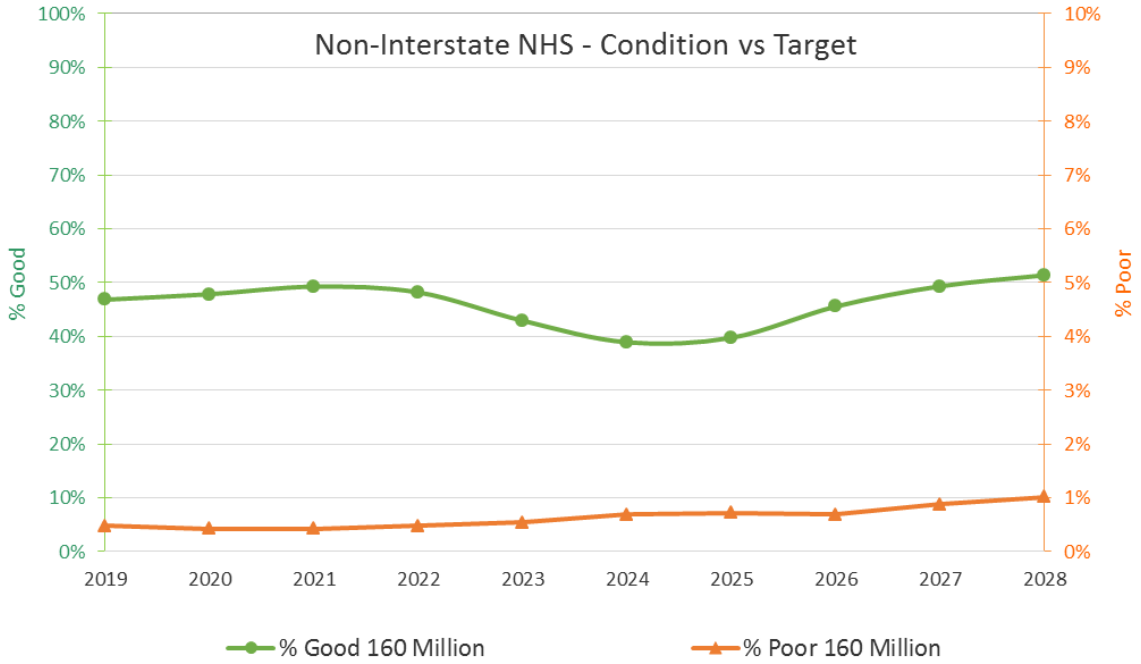

Figure 8-10: Non-Interstate NHS Condition 10-year Forecast with $160-million Budget

Figure 8-11 though Figure 8-13 are forecasts of the type of work that would be performed at each investment level. In general, the forecast is showing the predominance of the work is resurfacing and preservation treatments. Funding levels of $130 and $160 million show a large amount of pavement coming due for reconstruction in years 2024-2026. This is most likely the cause of the aforementioned dip in performance forecasted. Funding below $130 million in these years would have a significant impact on long-term performance as the model shows.

Bridge Investments

ITD directs approximately 20 percent of its bridge funding to preservation and 80 percent to restoration. ITD bridge investments are driven by its bridge condition performance measure. With a consistent funding stream of $80,000,000 to the bridge programs, ITD's models indicate that 80 percent of our bridges will be in good condition around the year of 2023. In subsequent years the bridge deterioration models indicates that bridge condition will be sustainable at that level of funding. See Figure 8-14. Specifically ITD believes that with this level of investment in all the State Highway System bridges, that bridges on the NHS will attain condition goals set out for them in the Poor and Good categories.

Appendix C - Declared Emergency Events 1997-2019

Idaho Flooding (DR-1177)
Incident period: March 14, 1997 to June 30, 1997
Major Disaster Declaration declared on June 13, 1997

Idaho Wildfires (DR-1341)
Incident period: July 27, 2000 to September 26, 2000
Major Disaster Declaration declared on September 01, 2000

Idaho Heavy Rains and Flooding (DR-1592)
Incident period: May 06, 2005 to May 20, 2005
Major Disaster Declaration declared on July 06, 2005

Idaho Severe Storms and Flooding (DR-1630)
Incident period: December 30, 2005 to January 04, 2006
Major Disaster Declaration declared on February 27, 2006

Idaho Flooding (DR-1781)
Incident period: May 15, 2008 to June 09, 2008
Major Disaster Declaration declared on July 31, 2008

Idaho Severe Storms and Flooding (DR-1927)
Incident period: June 02, 2010 to June 10, 2010
Major Disaster Declaration declared on July 27, 2010

Idaho Flooding, Landslides, and Mudslides (DR-1987)
Incident period: March 31, 2011 to April 11, 2011
Major Disaster Declaration declared on May 20, 2011

Idaho Severe Storm and Straight-line Winds (DR-4246)
Incident period: November 17, 2015
Major Disaster Declaration declared on December 23, 2015

Idaho Severe Winter Storms (DR-4252)
Incident period: December 16, 2015 to December 27, 2015
Major Disaster Declaration declared on February 01, 2016

Idaho Severe Winter Storms and Flooding (DR-4310)
Incident period: February 05, 2017 to February 27, 2017
Major Disaster Declaration declared on April 21, 2017

Idaho Severe Storms, Flooding, Landslides, and Mudslides (DR-4313)
Incident period: March 06, 2017 to March 28, 2017
Major Disaster Declaration declared on May 18, 2017

Idaho Flooding, Landslides, And Mudslides (DR-4333)
Incident period: May 06, 2017 to June 16, 2017
Major Disaster Declaration declared on August 27, 2017

Idaho Flooding (DR-4342)
Incident period: March 29, 2017 to June 15, 2017
Major Disaster Declaration declared on October 07, 2017

Idaho Severe Storms, Flooding, Landslides, And Mudslides (DR-4443)
Incident period: April 07, 2019 to April 13, 2019
Major Disaster Declaration declared on June 12, 2019
